Air Quality Index

A Guide to Air Quality and Your Health

Local air quality affects how we live and breathe. Like the weather, it can change from day to day or even hour to hour. The U.S. Environmental Protection Agency (EPA) and others are working to make information about outdoor air quality as available to the public as information about the weather. A key tool in this effort is the Air Quality Index, or AQI. EPA and local officials use the AQI to provide the public with timely and easy-to-understand information on local air quality and whether air pollution levels pose a health concern.

This booklet tells you about the AQI and how it is used to provide air quality information. It also tells you about the possible health effects of major air pollutants at various levels and suggests actions you can take to protect your health when pollutants in your area reach unhealthy concentrations.

What is the AQI?
The AQI is an index for reporting daily air quality. It tells you how clean or polluted your air is, and what associated health concerns you should be aware of. The AQI focuses on health effects that can happen within a few hours or days after breathing polluted air. EPA uses the AQI for five major air pollutants regulated by the Clean Air Act: ground-level ozone, particulate matter, carbon monoxide, sulfur dioxide, and nitrogen dioxide. For each of these pollutants, EPA has established national air quality standards to protect against harmful health effects.
How does the AQI work?

You can think of the AQI as a yardstick that runs from 0 to 500. The higher the AQI value, the greater the level of air pollution and the greater the health danger. For example, an AQI value of 50 represents good air quality and little potential to affect public health, while an AQI value over 300 represents hazardous air quality.

An AQI value of 100 generally corresponds to the national air quality standard for the pollutant, which is the level EPA has set to protect public health. So, AQI values below 100 are generally thought of as satisfactory. When AQI values are above 100, air quality is considered to be unhealthy—at first for certain sensitive groups of people, then for everyone as AQI values get higher.

Understanding the AQI

The purpose of the AQI is to help you understand what local air quality means to your health. To make the AQI as easy to understand as possible, EPA has divided the AQI scale into six categories, shown below:

<table>
<thead>
<tr>
<th>Air Quality Index (AQI) Values</th>
<th>Levels of Health Concern</th>
<th>Colors</th>
</tr>
</thead>
<tbody>
<tr>
<td>0 to 50</td>
<td>Good</td>
<td>Green</td>
</tr>
<tr>
<td>51 to 100</td>
<td>Moderate</td>
<td>Yellow</td>
</tr>
<tr>
<td>101 to 150</td>
<td>Unhealthy for Sensitive Groups</td>
<td>Orange</td>
</tr>
<tr>
<td>151 to 200</td>
<td>Unhealthy</td>
<td>Red</td>
</tr>
<tr>
<td>201 to 300</td>
<td>Very unhealthy</td>
<td>Purple</td>
</tr>
<tr>
<td>301 to 500</td>
<td>Hazardous</td>
<td>Maroon</td>
</tr>
</tbody>
</table>

Each category corresponds to a different level of health concern. For example, when the AQI for a pollutant is between 51 and 100, the health concern is “Moderate.” Here are the six levels of health concern and what they mean:

- **Good** The AQI value for your community is between 0 and 50. Air quality is considered satisfactory and air pollution poses little or no risk.
- **Moderate** The AQI for your community is between 51 and 100. Air quality is acceptable; however, for some pollutants there may be a moderate health concern for a very small number of individuals. For example, people who are unusually sensitive to ozone may experience respiratory symptoms.
- **Unhealthy for Sensitive Groups** Certain groups of people are particularly sensitive to the harmful effects of certain air pollutants. This means they are likely to be affected at lower levels than the general public. For example, children and adults who are active outdoors and people with respiratory disease are at greater risk from exposure to ozone, while people with heart disease are at greater risk from carbon monoxide. Some people may be sensitive to more than one pollutant. When AQI values are between 101 and 150, members of sensitive groups may experience health effects. The general public is not likely to be affected when the AQI is in this range.
- **Unhealthy** AQI values are between 151 and 200. Everyone may begin to experience health effects. Members of sensitive groups may experience more serious health effects.
- **Very Unhealthy** AQI values between 201 and 300 trigger a health alert, meaning everyone may experience more serious health effects.
- **Hazardous** AQI values over 300 trigger health warnings of emergency conditions. The entire population is more likely to be affected.

**AQI colors**

EPA has assigned a specific color to each AQI category to make it easier for people to understand quickly the significance of air pollution levels in their communities. For example, the color orange means that conditions are “unhealthy for sensitive groups”; the color red means that conditions may be “unhealthy” for everyone, and so on. You may see these colors when the AQI is reported in the newspaper or on television, or on your state or local air pollution agency’s website. The colors can help you rapidly determine whether air pollutants are reaching unhealthy levels in your area.
How is a community’s AQI calculated?

Air quality is measured by networks of monitors that record the concentrations of the major pollutants at more than a thousand locations across the country each day. These raw measurements are then converted into AQI values using standard formulas developed by EPA. An AQI value is calculated for each of the individual pollutants in an area (ground-level ozone, particulate matter, carbon monoxide, sulfur dioxide, and nitrogen dioxide). Finally, the highest of the AQI values for the individual pollutants becomes the AQI value for that day. For example, if on July 12 a certain area had AQI values of 90 for ozone and 88 for sulfur dioxide, the AQI value would be 90 for the pollutant ozone on that day.

When and how is the AQI reported to the public?

In large metropolitan areas (more than 350,000 people), state and local agencies are required to report the AQI to the public daily. When the AQI is above 100, they must also report which groups (e.g., children, people with asthma or heart disease) may be sensitive to the specific pollutant. If two or more pollutants have AQI values above 100 on a given day, agencies will report all the groups that are sensitive to those pollutants. Although it is not required, many smaller communities also report the AQI as a public health service.

Many metropolitan areas also report an AQI forecast that allows local residents to plan their activities to protect their health.

The AQI is a national index, so the values and colors used to show local air quality and the associated level of health concern will be the same everywhere you go in the U.S. Look for the AQI to be reported in your local newspaper, on television and radio, on the Internet, and on state and local telephone hotlines.

AQI in the Newspaper

Newspapers may use different formats to report the AQI. Here is one example:

Children active outdoors can be sensitive to some air pollutants.

AIR QUALITY INDEX

● AQI on the Internet

EPA’s AirNow web site (www.epa.gov/airnow) contains general information about air pollution plus real-time and forecast data for ground-level ozone. The web site also contains facts about the health and environmental effects of air pollution, steps you can take to protect your health and reduce pollution, and links to state and local air pollution control agency web sites with local AQI information.

What are typical AQI values in most communities?

In many U.S. communities, AQI values are mostly below 100, with values greater than 100 occurring several times a year. Several metropolitan areas in the United States have more severe air pollution problems, and the AQI in these areas may often exceed 100. AQI values higher than 200 are very infrequent, and AQI values above 300 are extremely rare.

AQI values can vary significantly from one season to another. In winter, for example, carbon monoxide is likely to be the pollutant with the highest AQI values in some areas, because cold weather makes it difficult for car emission control systems to operate effectively. In summer, ozone is the most significant air pollutant in many communities, since it forms in the presence of heat and sunlight.

AQI values also can vary depending on the time of day. For example, ozone levels often peak in the afternoon, while carbon monoxide is usually a problem during morning or evening rush hours.

How can I avoid being exposed to harmful air pollutants?

The following charts and text tell you where each pollutant comes from, what health effects may occur for each pollutant, and what you can do to protect your health.

### Air Quality Index (AQI): Ozone

*Generally, an AQI of 100 for ozone corresponds to an ozone level of 0.08 parts per million (averaged over 8 hours).

What is ozone?

Ozone is an odorless, colorless gas composed of three atoms of oxygen. Ozone occurs both in the Earth’s upper atmosphere and at ground level. Ozone can be good or bad, depending on where it is found.

**Good Ozone.** Ozone occurs naturally in the Earth’s upper atmosphere—10 to 30 miles above the Earth’s surface—where it forms a protective layer that shields us from the sun’s harmful ultraviolet rays. This beneficial ozone is gradually being destroyed by manmade
chemicals. An area where ozone has been significantly depleted—for example, over the North or South pole—is sometimes called a “hole in the ozone.”

- **Bad Ozone.** In the Earth’s lower atmosphere, near ground level, ozone is formed when pollutants emitted by cars, power plants, industrial boilers, refineries, chemical plants, and other sources react chemically in the presence of sunlight. Ozone at ground level is a harmful pollutant. Ozone pollution is a concern during the summer months, when the weather conditions needed to form it—lots of sun, hot temperatures—normally occur.

The risk of exposure to unhealthy levels of ozone is greatest during summer months.

**What are the health effects and who is most at risk?**

Roughly one out of every three people in the United States is at a higher risk of experiencing ozone-related health effects. Sensitive people include children and adults who are active outdoors, people with respiratory disease, such as asthma, and people with unusual sensitivity to ozone.

- One group at high risk from ozone exposure is active children because this group often spends a large part of the summer playing outdoors. However, people of all ages who are active outdoors are at increased risk because, during physical activity, ozone penetrates deeper into the parts of the lungs that are more vulnerable to injury.

- People with respiratory diseases that make their lungs more vulnerable to ozone may experience health effects earlier and at lower ozone levels than less sensitive individuals.

- Though scientists don’t yet know why, some healthy people experience health effects at more moderate levels of outdoor exertion or at lower ozone levels than the average person.

- Ozone can irritate the respiratory system, causing coughing, throat irritation, and/or an uncomfortable sensation in the chest.

- Ozone can reduce lung function and make it more difficult to breathe deeply and vigorously. Breathing may become more rapid and shallow than normal. This reduction in lung function may limit a person’s ability to engage in vigorous outdoor activities.

- Ozone can aggravate asthma. When ozone levels are high more people with asthma have attacks that require a doctor’s attention or the use of additional medication. One reason this happens is that ozone makes people more sensitive to allergens, the most common triggers of asthma attacks.

- Ozone can increase susceptibility to respiratory infections.

- Ozone can inflame and damage the lining of the lungs. Within a few days, the damaged cells are shed and replaced—much like the skin peels after a sunburn. Animal studies suggest that if this type of inflammation happens repeatedly over a long time period (months, years, a lifetime), lung tissue may become permanently scarred, resulting in less lung elasticity, permanent loss of lung function, and a lower quality of life.
What is particulate matter?

The term “particulate matter” (PM) includes both solid particles and liquid droplets found in air. Many manmade and natural sources emit PM directly or emit other pollutants that react in the atmosphere to form PM. These solid and liquid particles come in a wide range of sizes. Particles less than 10 micrometers in diameter tend to pose the greatest health concern because they can be inhaled into and accumulate in the respiratory system. Particles less than 2.5 micrometers in diameter are referred to as “fine” particles. Sources of fine particles include all types of combustion (motor vehicles, power plants, wood burning, etc.) and some industrial processes. Particles with diameters between 2.5 and 10 micrometers are referred to as “coarse.” Sources of coarse particles include crushing or grinding operations, and dust from paved or unpaved roads.

What are the health effects and who is most at risk?

Both fine and coarse particles can accumulate in the respiratory system and are associated with numerous health effects. Coarse particles can aggravate respiratory conditions such as asthma. Exposure to fine particles is associated with several serious health effects, including premature death. Adverse health effects have been associated with exposures to PM over both short periods (such as a day) and longer periods (a year or more).

- When exposed to PM, people with existing heart or lung diseases—such as asthma, chronic obstructive pulmonary disease, congestive heart disease, or ischemic heart disease—are at increased risk of admission to hospitals or emergency rooms.
- The elderly also are sensitive to PM exposure. They are at increased risk of admission to hospitals or emergency rooms and premature death from heart or lung diseases.
- PM can increase susceptibility to respiratory infections and can aggravate existing respiratory diseases, such as asthma and chronic bronchitis, causing more use of medication and more doctor visits.
**Air Quality Index (AQI): Carbon Monoxide (CO)**

<table>

</tr>
</tbody>
</table>

* An AQI of 100 for carbon monoxide corresponds to a CO level of 9 parts per million (averaged over 8 hours).

**What is carbon monoxide?**

Carbon monoxide (CO) is an odorless, colorless gas. It forms when the carbon in fuels does not completely burn. Vehicle exhaust contributes roughly 60 percent of all carbon monoxide emissions nationwide, and up to 95 percent in cities. Other sources include fuel combustion in industrial processes and natural sources such as wildfires. Carbon monoxide concentrations typically are highest during cold weather, because cold temperatures make combustion less complete and cause inversions that trap pollutants low to the ground.

**What are the health effects and who is most at risk?**

Carbon monoxide enters the bloodstream through the lungs and binds chemically to hemoglobin, the substance in blood that carries oxygen to cells. In this way, carbon monoxide reduces the amount of oxygen reaching the body’s organs and tissues.

- **People with cardiovascular disease, such as angina,** are most at risk from carbon monoxide. These individuals may experience chest pain and more cardiovascular symptoms if they are exposed to carbon monoxide, particularly while exercising.

- **People with marginal or compromised cardiovascular and respiratory systems** (for example, individuals with congestive heart failure, cerebrovascular disease, anemia, chronic obstructive lung disease), and possibly fetuses and young infants, may also be at greater risk from carbon monoxide pollution.

- **In healthy individuals,** exposure to higher levels of carbon monoxide can affect mental alertness and vision.

Vehicle exhaust contributes roughly 60 percent of all carbon monoxide emissions nationwide.

Vehicle exhaust contributes roughly 60 percent of all carbon monoxide emissions nationwide.
Air Quality Index (AQI): Sulfur Dioxide (SO₂)

</tbody>
</table>

* An AQI of 100 for sulfur dioxide corresponds to an SO₂ level of 0.14 parts per million (averaged over 24 hours).

What is sulfur dioxide?
Sulfur dioxide (SO₂), a colorless, reactive gas, is produced during the burning of sulfur-containing fuels such as coal and oil, during metal smelting, and by other industrial processes. Major sources include power plants and industrial boilers. Generally, the highest concentrations of sulfur dioxide are found near large industrial sources.

What are the health effects and who is most at risk?
- Children and adults with asthma who are active outdoors are most vulnerable to the health effects of sulfur dioxide. The primary effect they experience, even with brief exposure, is a narrowing of the airways (called bronchoconstriction), which may cause symptoms such as wheezing, chest tightness, and shortness of breath. Symptoms increase as sulfur dioxide concentrations and/or breathing rates increase. When exposure ceases, lung function typically returns to normal within an hour.
- At very high levels, sulfur dioxide may cause wheezing, chest tightness, and shortness of breath in people who do not have asthma.
- Long-term exposure to both sulfur dioxide and fine particles can cause respiratory illness, alter the lung’s defense mechanisms, and aggravate existing cardiovascular disease. People who may be most susceptible to these effects include individuals with cardiovascular disease or chronic lung disease, as well as children and the elderly.
What is nitrogen dioxide?
Nitrogen dioxide (NO₂) is a reddish brown, highly reactive gas formed when another pollutant (nitric oxide) combines with oxygen in the atmosphere. Once it has formed, nitrogen dioxide reacts with other pollutants (volatile organic compounds). Eventually these reactions result in the formation of ground-level ozone. Major sources include automobiles and power plants.

What are the health effects and who is most at risk?

- In children and adults with respiratory disease, such as asthma, nitrogen dioxide can cause respiratory symptoms such as coughing, wheezing, and shortness of breath. Even short exposures to nitrogen dioxide affect lung function.
- In children, short-term exposure can increase the risk of respiratory illness.
- Animal studies suggest that long-term exposure to nitrogen dioxide may increase susceptibility to respiratory infection and may cause permanent structural changes in the lungs.

### Air Quality Index (AQI): Nitrogen Dioxide (NO₂)

</tbody>
</table>

* Short-term health effects for nitrogen dioxide do not occur until AQI values are above 200; therefore, the AQI is not calculated below 201 for NO₂. An AQI of 201 for NO₂ corresponds to an NO₂ level of 0.65 parts per million (averaged over 24 hours).

For more information on air quality in your area, visit EPA’s AirNow web site at [http://www.epa.gov/airnow](http://www.epa.gov/airnow) or call EPA’s Office of Air and Radiation at (202) 564-7400.

For technical information on reporting the AQI, see EPA’s publication Guideline for Reporting of Daily Air Quality—Air Quality Index (AQI), EPA-454/R-99-010, at [http://www.epa.gov/airnow/publications.html](http://www.epa.gov/airnow/publications.html).

The focus of the AQI is on outdoor air quality. For information on indoor air quality, contact EPA’s Indoor Air Quality Information Clearinghouse at (800) 438-4318.
