**Subject:** Background Concentrations of Metals in Groundwater - Miami-Dade County

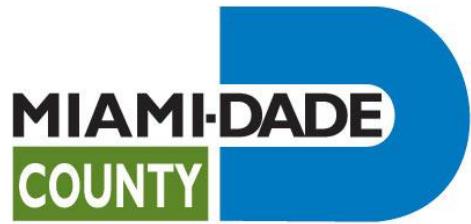

---

Between November 2019 and January 2020 DERM commissioned a study to evaluate background concentrations of certain nutrients and metals in shallow groundwater throughout the County. The project involved the sampling and analysis of groundwater from over 500 pre-existing monitoring wells in Miami-Dade County. The attached report presents the results, data analysis and findings of the study with respect to background concentrations of the metals of interest.

Overall, the background concentrations of metals in shallow groundwater in Miami-Dade County is unremarkable. Eight of the metals evaluated reported non-detectable concentrations in greater than ninety percent of the samples. Four metals, arsenic, aluminum, iron, and manganese documented concentrations above regulatory criteria defined as the groundwater cleanup target levels (GCTL) pursuant to Chapter 62-777 Florida Administrative Code (FAC) and Chapter 24 of the Miami-Dade County Code. Except for iron, the frequency of GCTL exceedance was less than ten percent.

The GCTL for arsenic is based on potential impacts to human health. While human health-based benchmarks (HHB) are available for aluminum, manganese and iron the GCTLs for these metals are based on organoleptic concerns (color, taste, smell) and the potential to cause nuisance concerns, since these effects occur at much lower concentrations than the concentrations at which human health impacts are documented. Arsenic, manganese, and iron were documented in the studied groundwater at concentrations exceeding the human health-based criteria (HHB) in a small percent of the samples.

The distribution of metals in groundwater was evaluated for potential impacts based on groundwater geochemistry as well as surrounding land use. Spatial trends in metal concentration distribution were also assessed.

## BACKGROUND CONCENTRATION OF METALS IN GROUNDWATER - MIAMI-DADE COUNTY

August 2022

Department of Regulatory and Economic Resources (RER)  
Division of Environmental Resources Management (DERM)

## **Introduction**

The Miami-Dade County Department of Regulatory and Economic Resources Division of Environmental Resources Management (DERM) currently administers two groundwater quality monitoring programs (WQMP): the Wellfield Protection Area Monitoring Program (WMP) required pursuant to Miami-Dade County's Consumptive Water Use Permit issued by the South Florida Water Management District and the Ambient Groundwater Monitoring Program (AGWMP), established in 1981 to provide data on Miami-Dade County's background groundwater quality. Between the two programs DERM routinely samples a total of 254 groundwater monitoring wells (monitoring wells): one hundred and eighty-five (185) wells in the WMP and sixty-nine (69) in the AGWMP. The monitoring well depths range from 10 to 149 feet below land surface (bls). Groundwater is monitored for a comprehensive list of parameters at differing frequencies based on the requirements of each program. Data from groundwater monitoring programs is updated on a weekly basis and is publicly accessible via the Miami-Dade County Surface and Groundwater Quality Viewer at <https://mdc.maps.arcgis.com/apps/webappviewer/index.html?id=3fd24515ee614f5db63924d7323a4ea7>.

Recent challenges relating to sea level rise, concerns regarding the potential impact to groundwater resources from compromised septic tanks and emerging contaminants, land use changes and increased development has indicated a need to supplement the available regional groundwater quality data especially for urbanized areas of the county.

In response to the identified need, during November 2019 through January 2020, DERM (through its environmental contractor) conducted a synoptic groundwater sampling event. The concentrations of fourteen metals nutrients and, to a limited sucralose as wells as four pharmaceuticals, in shallow groundwater in the urban areas of Miami-Dade County (MDC) was evaluated utilizing samples collected from 552 pre-existing wells located at facilities permitted by the Miami-Dade County Division of Environmental Resources Management (DERM). The fourteen metals analyzed Aluminum (Al), Arsenic (As), Barium (Ba), Cadmium (Cd), Chromium (Cr), Copper (Cu), Iron (Fe), Lead (Pb), Manganese (Mn), Nickel (Ni), Selenium (Se), Silver (Ag), Vanadium (V) and Zinc (Zn) are the report focus of this report.

## **Purpose and Scope**

The locations sampled for this study are assumed to be unimpacted by any potential point source or non-point source discharges of the metals of interest and as such groundwater concentrations at these locations potentially represent anthropogenic background concentrations for the urbanized areas of the county. The primary purpose of the study was to describe the occurrence and distribution of the fourteen metals in shallow groundwater in MDC and to determine regional background concentrations for these metals. The metals were also evaluated against their groundwater cleanup target levels (GCTL) pursuant to the Miami-Dade County Code (Chapter 24) and Florida Department of Environmental Protection criteria (Chapter 62-777, Florida Administrative Code) to identify subregions where impacted groundwater (groundwater at concentrations above GCTL) may occur based on localized geochemistry. The study also assessed for patterns in spatial distribution of the metals, for those metals with concentrations above criteria.

## Study Design

Gas stations are required by permit to maintain compliance monitoring wells. The locations sampled for this project (Figure 1 and Table 2) were selected from DERM's records of active gas stations in Miami-Dade County (MDC). Except where two or more gas stations fell within a 500 feet radius of each other, in which case only one such location was randomly selected for sampling, all active gas stations in MDC were sampled. Twelve of the sampling locations represented industrial facilities, not gas stations. In most cases the selected facilities had several compliance monitoring wells; however, typically only one monitoring well was sampled at each facility. Monitoring well selection criteria included proximity to a septic tank or to an adjacent surface water body (for the evaluation of nutrients), minimization of disturbance to facility operations, safety, accessibility, etc.

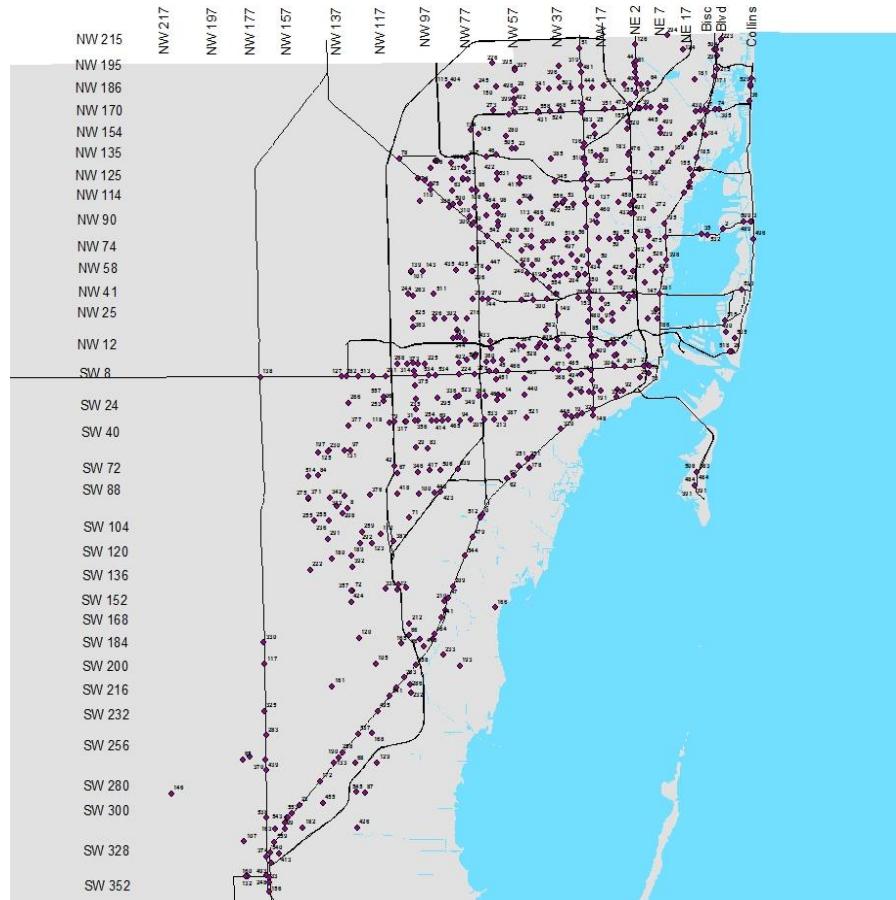

Figure 1: Sampling Locations (Table 2)

Sampling locations were identified by a seven-digit state ID number assigned to the facility; the sampled well was identified and located based on its geographic coordinate. Sampling was conducted by Arcadis, US Inc., under contract with DERM.

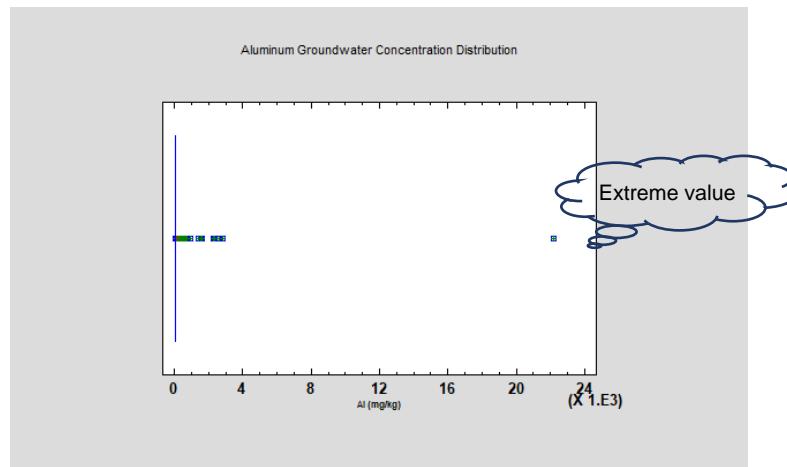

## Sampling Methodology

Prior to sample collection, the wells were purged and geochemical parameters, temperature, dissolved oxygen (DO), specific conductance and pH, were allowed to stabilize. The wells were sampled in accordance with the Florida Department of Environmental Protection (FDEP) Standard Operating Procedures provided in Chapter 62-160, Florida Administrative Code (FAC) <https://floridadep.gov/dear/quality-assurance/content/dep-sops>. The samples were placed on ice and transported to the DERM laboratory.

The samples were analyzed either by the DERM laboratory or by Pace Analytical Laboratory utilizing EPA method 200.7. For some metals, the two analytical laboratories reported at different detection limits (both detection limits were below applicable groundwater regulatory criteria); in such cases the highest detection limit was used for statistical evaluations.

## Statistical Approach

The handling of outliers in environmental data represents a challenge since an anomalous observation does not necessarily mean that the data is wrong or false. Since the objective of the study was to describe the background groundwater concentrations and given the potential influences of heterogeneous groundwater geochemistry, soil type, and aquifer characteristics the data was not censored for outliers using the commonly utilized censoring techniques (e.g., Dixon's test, Rosner test, etc.). Instead, the data was censored to remove extreme values only. Aluminum (Figure 2), Ba, Cr, Pb, Mn and Ni had one extreme value while Cu, Ag and Zn had two. Data from monitoring wells with multiple samples (duplicate samples, resampled sites, etc.) were represented as the mean of the concentrations except when resampling was based on the existence of an extreme value in which case the extreme value was excluded as indicated above and exemplified by Figure 2.

## Data Evaluation

### Groundwater Geochemistry

Temperature, specific conductance, pH, and DO were obtained as field measurements during each sampling event. Groundwater temperature ranged from 22.8°C to 32.79°C (median 27.7°C). Specific conductance ranged from 136 µS/cm to 4342 µS/cm with a median concentration of 477 µS/cm categorizing the groundwater documented during this study as fresh (<1500 µS/cm) to slightly saline (1500 to 4600 µS/cm) (Kasenow, 1997). pH values ranged from 5.97 to 8.78, (exclusive of four anomalous values 2.37, 3.01, 4.3 and 10.04) with a median of 7.2, which is higher than the median value of 6.7 documented for Miami-Dade, Broward, and Palm Beach Counties by Bradner (Bradner et.al. 2005). Seventy six percent of the pH values fell between 7 and 8 (Figure 3).

The National Oceanographic and Atmospheric Administration defines waters with DO levels between 0 to 0.2 mg/l as anoxic and DO levels between 0.3 and 2 mg/l as hypoxic (NOAA Chesapeake Bay). Waters with DO above 3 mg/l are considered oxic or oxygenated. The median dissolved oxygen concentration of 0.35 mg/l indicated groundwater in this study area is oxygen deficient and classifies as predominantly anoxic or hypoxic water (Figure 4) which is consistent with the USGS findings for predominately carbonate rock aquifers (DeSimone et.al. 2015).

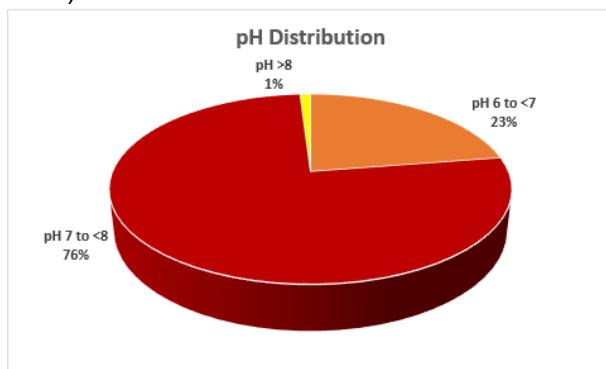

Figure 3: Percent distribution of pH in groundwater

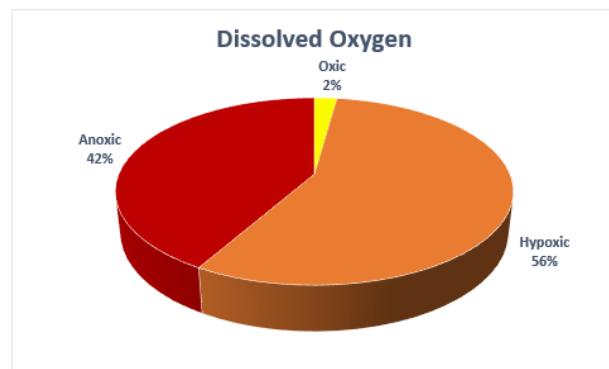

Figure 4: Percent of samples per DO saturation category

Several studies have documented the influence of organic matter on the solubility and mobility of metals in groundwater with the primary mechanisms of action being the impact on redox reactions, formation of metal complexes and sorption and desorption process. TOC along with dissolved organic carbon are the two primary parameters used as indicators of overall levels of organic compounds in groundwater. Forty-one samples were analyzed for total organic carbon (TOC), concentrations ranged from 1000 µg/l to 7300 µg/l with one extreme outlier, 38400 µg/l.

### Occurrence of Metal in Groundwater

Over 90 percent of the samples for Arsenic, Cadmium, Chromium, Copper, Lead, Nickel, Silver, and Selenium were reported at below the method detection limit (for parameters with multiple detection limits the largest detection limit was utilized). Except for arsenic, metals with greater than 90% non-detects were not further evaluated. Barium was ubiquitous in groundwater with a

## Background Concentrations of Metals in Groundwater-Miami-Dade County

detection frequency of 99.3 percent; however, barium concentrations did not exceed the Groundwater Cleanup Target Level (GCTL) provided in 62-777 FAC and Chapter 24 of the MDC Code (GCTL) therefore, barium was not further evaluated. Similarly, vanadium and zinc were not further evaluated since they were not detected at concentrations above the GCTL.

Approximately 35 percent of all samples exceeded the GCTL for at least one metal while approximately 8 percent exceed for two or more metals. Excursions from the GCTL were documented for four metals: aluminum, arsenic, iron, and manganese. In the case of lead one sample exceeded the GCTL but the concentration was classified as an extreme value. The GCTL for arsenic is based on human health concerns and is equivalent to the primary drinking water standard developed by the U.S Environmental Protection Agency (USEPA) to be protective of human health. Aluminum, iron, and manganese are assigned secondary drinking water standards by the USEPA based on aesthetic considerations, such as taste, color, and odor. While human health risk-based criteria are available for these metals (iron 4200 µg/l, manganese 330 µg/L and Aluminun 7000 µg/l - FDEP) the regulatory criteria pursuant to 62-777 FAC and Chapter 24 of the MDC Code is the organoleptic/aesthetic end point. These organoleptic endpoints are significantly lower than the human health-based (HHB) criteria and are therefore adequate to be protective of human health effects.

\* MDL PACE Laboratory/DERM Laboratory

\*\* Extreme Value(s) not included for statistical calculations

Arsenic exceeded the GCTL in 3.4 percent of the samples analyzed. Twenty-eight (28) percent of samples for iron (extreme values not included in data evaluation) and 6 percent of the aluminum and manganese samples exceeded the GCTL based on the organoleptic endpoint. Table 1. Manganese exceeded its HHB at a frequency of 3.6 percent while the frequency of

## Background Concentrations of Metals in Groundwater-Miami-Dade County

HHB exceedance for iron was 1.3 percent. In total 7.8 percent of samples exceeded the HHB. Figure 5.

A desktop assessment (Florida Department of Health potable well database, Miami-Dade Water and Sewer customer database and DERM potable water supply permit database) of the locations with groundwater exceedances of the HHB indicates that these locations and adjoining properties are not documented to be served by private wells.

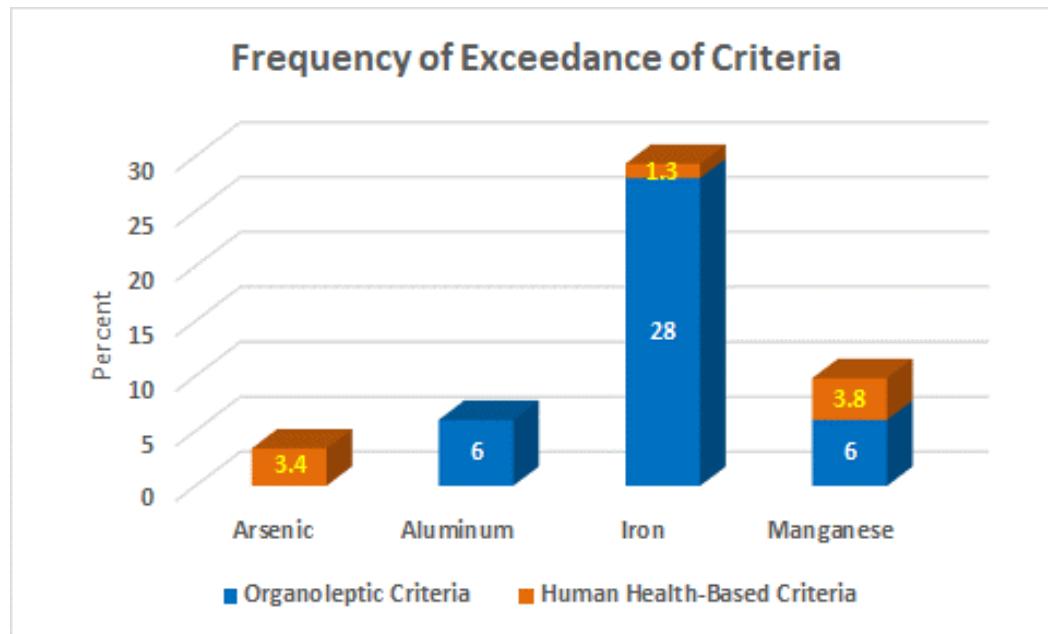

Figure 5: Frequency of exceedance of GCTL and HHB

Aluminum concentrations ranged from below detection limit (MDL 30.7 µg/l) to 2790 µg/l, arsenic concentrations ranged from below detection limit (MDL 7.1) to 30.7 µg/l while manganese concentrations ranged from 0.4 µg/l to 3640 µg/l. Iron exhibited the most variability with respect to the magnitude of concentrations: ranging over four orders of magnitude from 4.5 µg/l to 11,400 µg/l (Table 1)

Several samples reported multiple metals with GCTL exceedances. In all cases with multiple exceedances iron was one of the co-occurring metals; iron co-occurred with aluminum most frequently (Figure 6). The Spearman Ranked Correlation analysis indicated positive correlations between iron and aluminum and iron and manganese ( $r= 0.3$  and  $r=0.6$  respectively). With respect to co-occurrence for samples exceeding the HHB criteria, one sample exceeded the HHB for all three metals while exceedances of arsenic and iron were documented in two additional samples.

The transformation of inorganic contaminants in groundwater is influenced by the chemical and physical characteristics of aquifers such as pH, redox potential (Eh) and organic matter. Aluminum, iron, manganese, nickel, copper, lead, and zinc, adsorb more strongly to aquifer materials as pH increases (USGS 2011). Consequently, for such metals, solubility in water often decreases with increasing pH while for others, such as arsenic, solubility can increase with increasing pH over the normal pH range of most natural waters (USGS 2011). Reducing

## Background Concentrations of Metals in Groundwater-Miami-Dade County

conditions, and salinity are some of the key factors influencing the dissolution and migration of Fe and Mn to groundwater (Zhang et. al., 2020). High concentrations of dissolved iron or manganese (defined as greater than or equal to 50 µg/L) indicate that the aquifer geochemical environment is relatively free of dissolved oxygen and dissolved sulfide (Groschen, et.al., 2009).

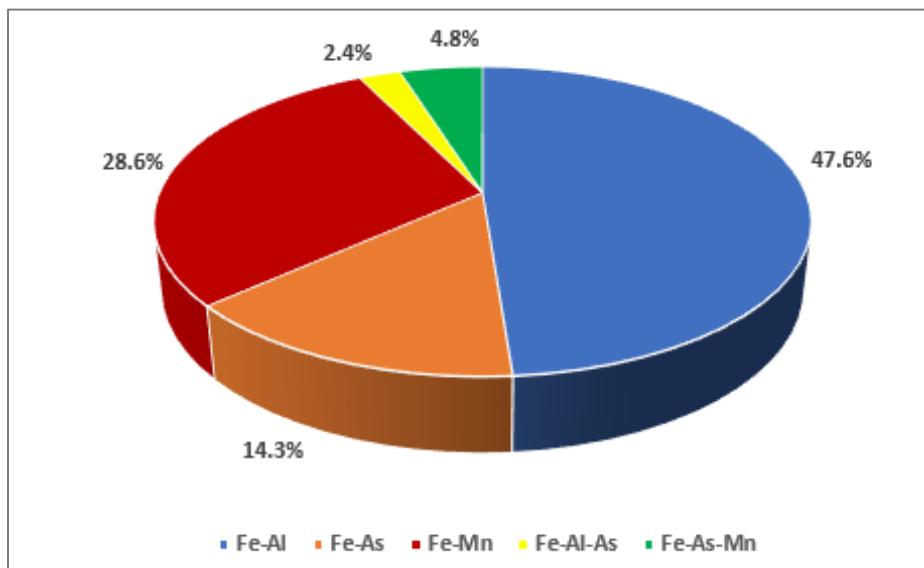

Figure 6: Frequency of co-occurrence of metals >GWCTL

The potential influence of groundwater geochemistry (pH, temperature, specific conductivity, DO and TOC) on the distribution of Al, Fe, Mn, and As was evaluated. The Spearman Ranked correlation indicated a weak to moderate negative correlation between Fe and DO as well as Fe and pH ( $r = -0.2$  and  $r = -0.3$ ) while exhibiting a weak to moderate positive correlation with specific conductance. Correlations were also observed for Mn with DO, pH, and specific conductance ( $r = -0.3$ ,  $r = -0.3$  and  $r = 0.3$ , respectively). Arsenic was not significantly correlated with any geochemical variable. For the samples for which TOC values were available, iron and manganese indicated significant positive correlations (Spearman Ranked coefficient) with  $r = 0.53$ , and  $r = 0.58$  respectively while aluminum indicated a weak negative correlation ( $r = -0.23$ ).

### Spatial Distribution

Aluminum, iron, and manganese were evaluated for spatial distribution patterns along north to south and west to east transects across MDC (Figure 7). For north to south spatial analysis the County was divided into three geographic regions: north, center and south. The regions were roughly based on inland extrapolation of the North Bay, North Central Inshore and South Central Inshore boundaries as defined by the Florida Department of Environmental Protection's numerical nutrient criteria estuary regions (FDEP Numeric Nutrient Criteria (NNC) - Estuary Nutrient Regions - [FDEP::numeric-nutrient-criteria-nnc-estuary-nutrient-regions](#)) and were initially demarcated to facilitate the nutrient evaluation portion of the larger project.

Within each geographic region the data was further evaluated along east-west transects to evaluate the impact of urbanization since generally the western reaches of the county represent more recently urbanized areas and given the general groundwater flow direction as provided by Fish and Stewart (USGS 1991) represent upstream/headwaters.

## Background Concentrations of Metals in Groundwater-Miami-Dade County

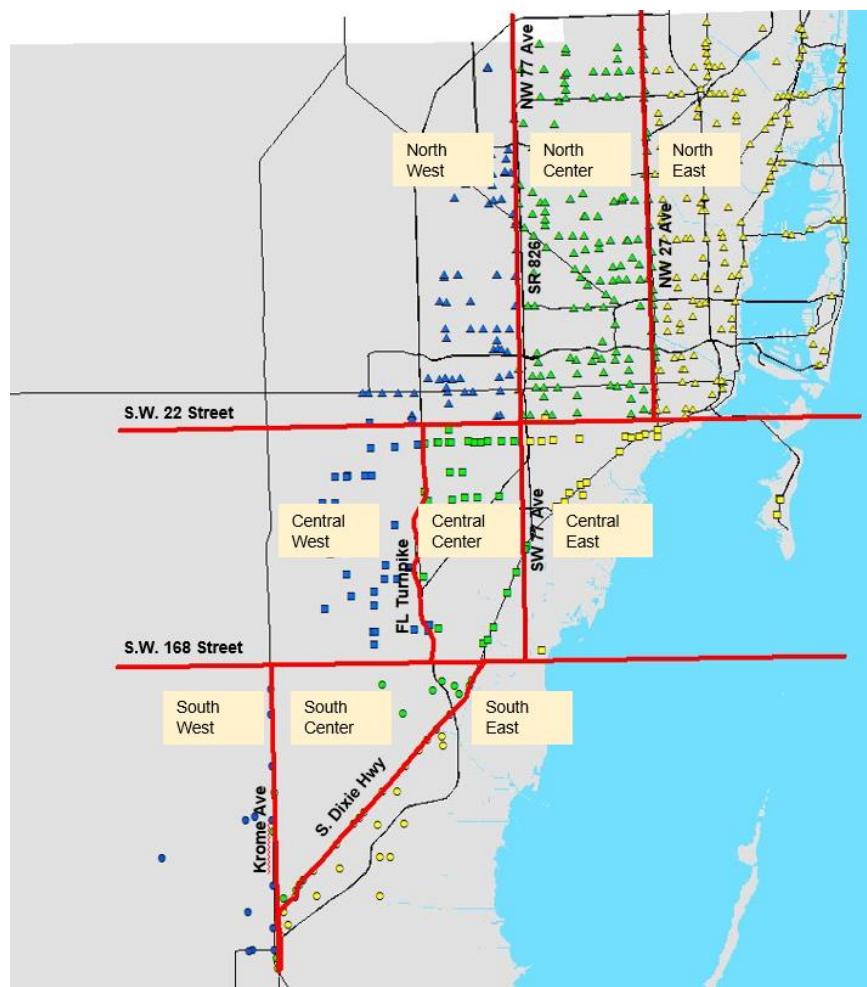

Figure 7: Spatial Distribution Boundaries

Iso-concentration maps for aluminum, iron and manganese are provided in Figures 8a, b, and c. Highest concentrations of iron and aluminum were documented in the north: the population distributions and median concentrations for these two parameters indicated no significant differences between the central and south regions of the county (Figure 9). Manganese concentrations indicated no significant north-central-south spatial variability (Figure 9). None of the metals evaluated indicated statistically significant east to west spatial distribution patterns.

Notwithstanding the absence of overall statistically significant north to south differences in spatial distribution for manganese the data indicated a cluster of high manganese concentrations in the central region of the county (Figure 8c). Although the central region accounted for only 19 percent of the total number of samples obtained for manganese it accounted for a disproportionate number of all manganese GCTL exceedances, specifically, 33 percent.

This disproportionality is also evident in the spatial distribution of samples exceeding the HHB for manganese where in the central region 93% of the samples above GCTL for manganese also exceeded the HHB while in the north only 33% of the samples above GCTL exceeded the HHB. The data appears to suggest that the aquifer geochemistry in the central region of the

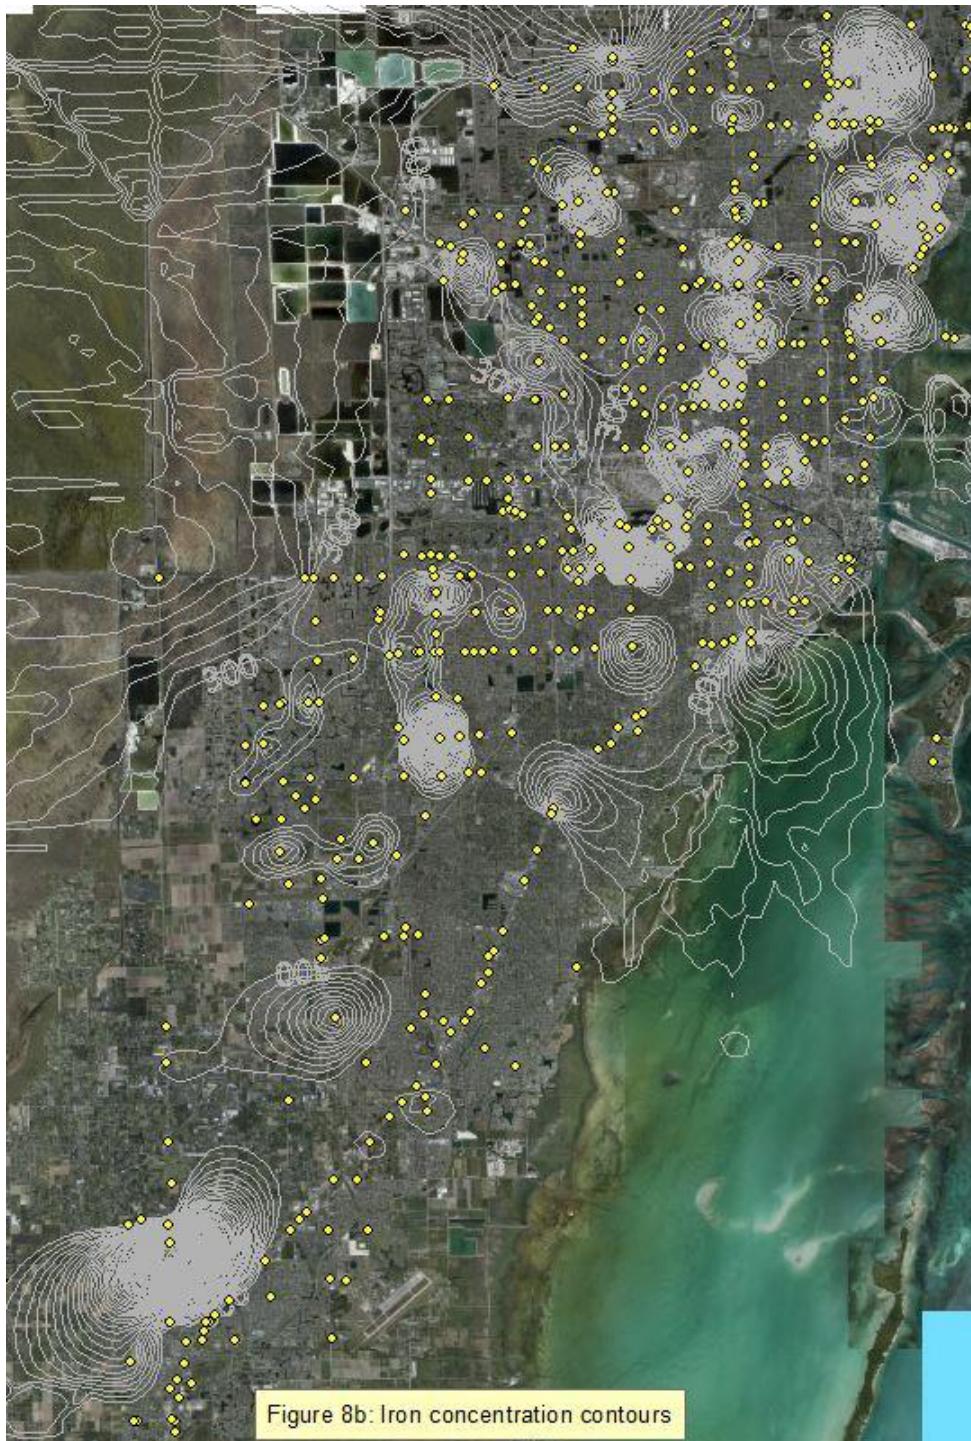

## Background Concentrations of Metals in Groundwater-Miami-Dade County

county is conducive to the desorption and mobilization of manganese. The proportion of samples exceeding HHB relative to those exceeding the GCTL for iron did not indicate a spatial bias. The ratio was 3.7 percent for the north and 3.4 percent for the central region.

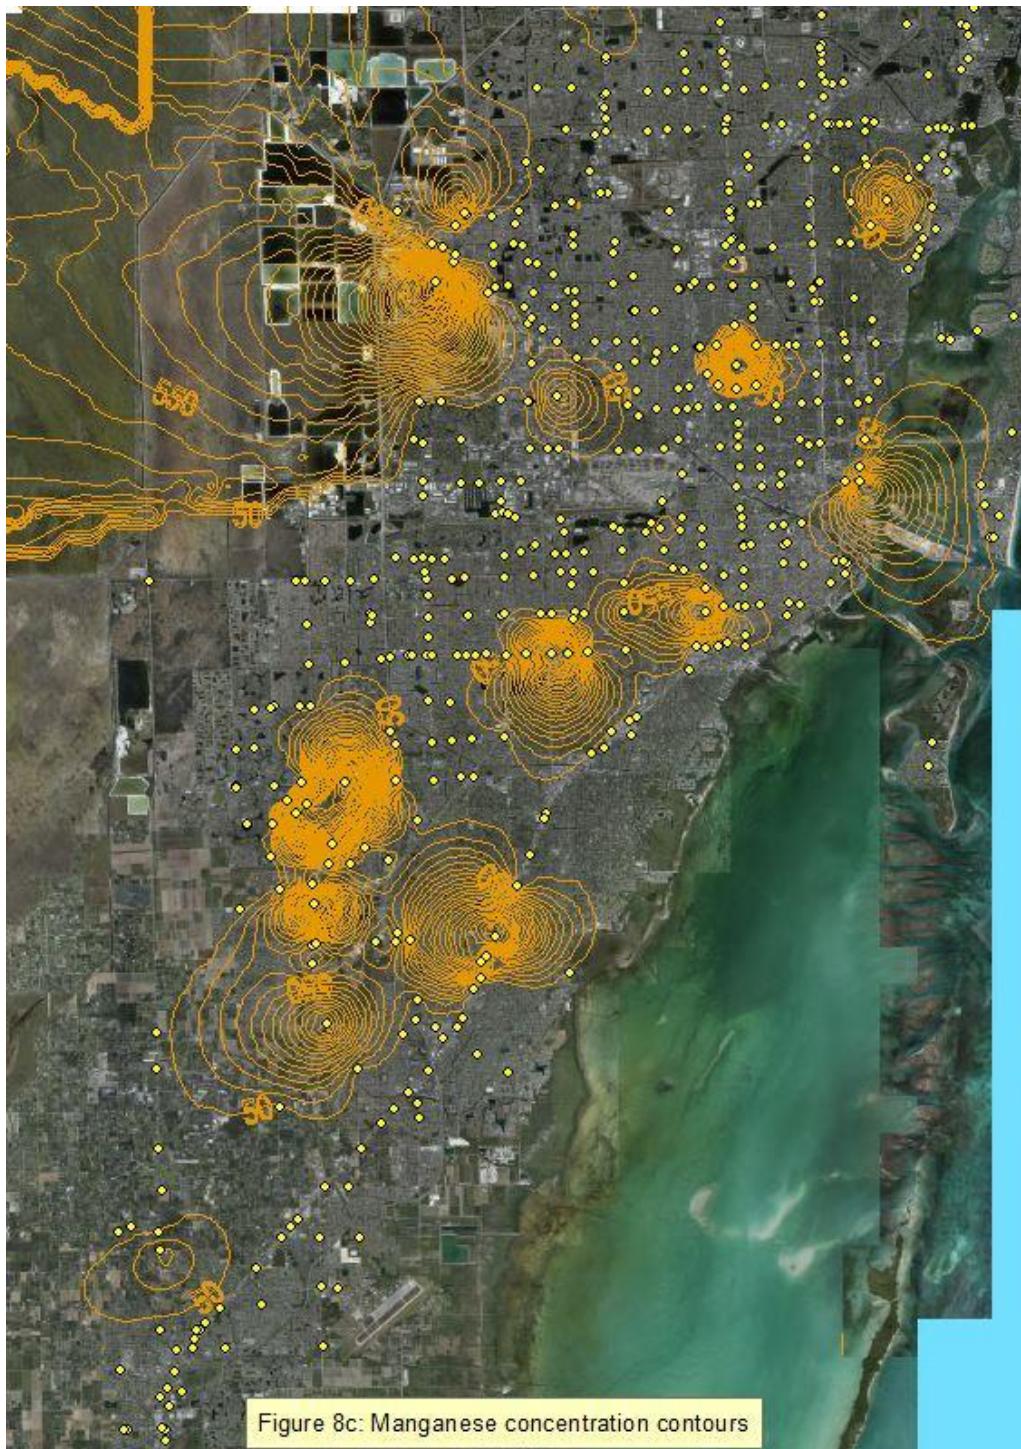

Arsenic concentration distribution indicated no spatial variability, neither did the percentage of samples exceeding the GCTL/HHB for arsenic.

Background Concentrations of Metals in Groundwater-Miami-Dade County

Background Concentrations of Metals in Groundwater-Miami-Dade County

## Background Concentrations of Metals in Groundwater-Miami-Dade County

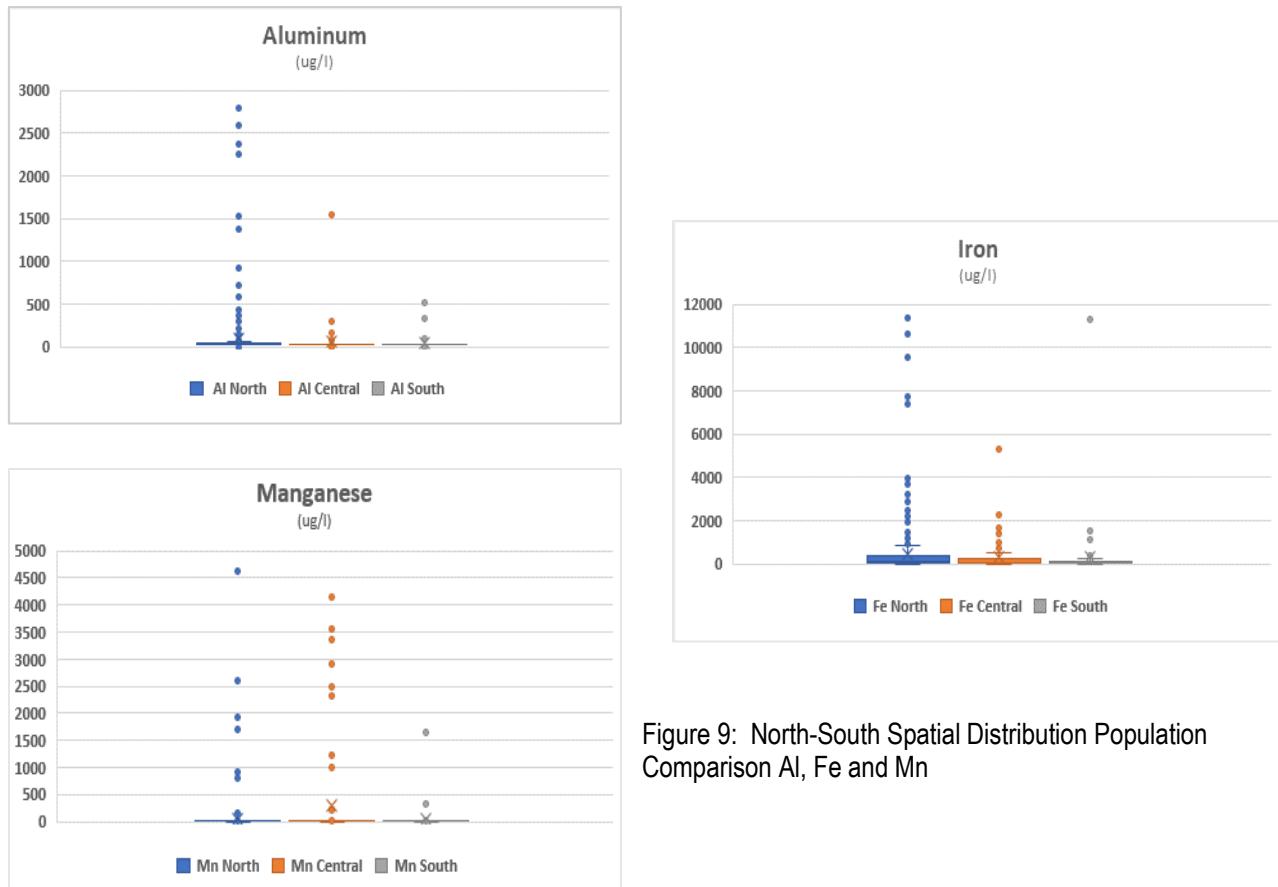

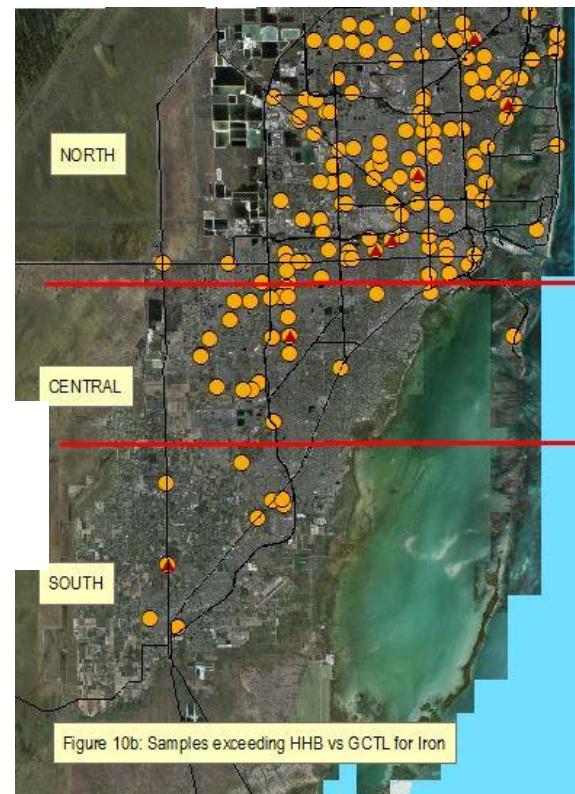

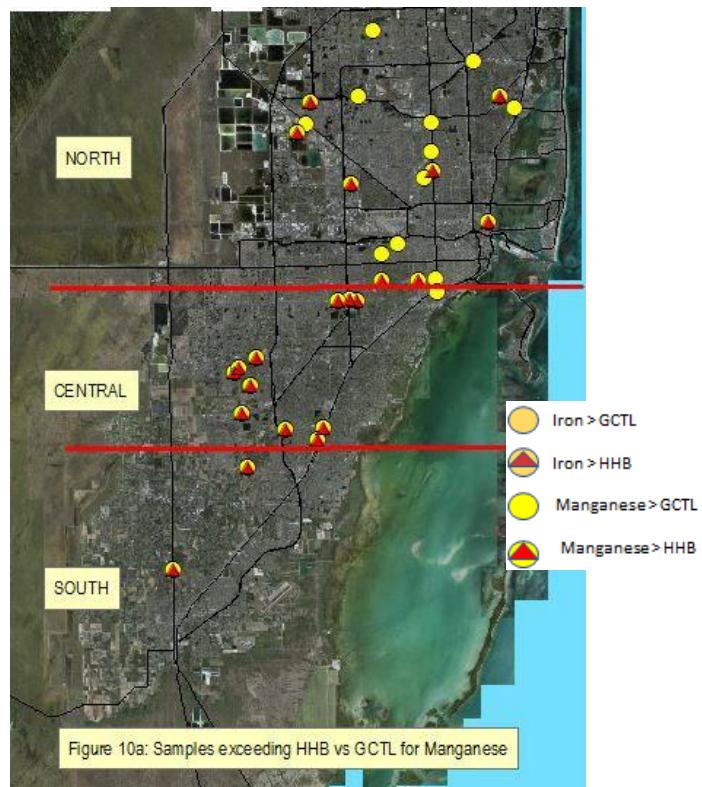

Figure 9: North-South Spatial Distribution Population Comparison Al, Fe and Mn

## Background Concentrations of Metals in Groundwater-Miami-Dade County

Evaluation of the groundwater data with respect to the geochemical factors know to influence and control the occurrence, transformation, and mobility of metal in groundwater did not provide a potential explanation for the observed spatial distributions.

### Land Use

Industrial/commercial agricultural, and residential land uses were selected as land uses of interest for the purpose of this study. The aluminum, iron and manganese data sets were evaluated for any indication of differences in the groundwater quality based on the predominant surrounding land use. Figure 11.

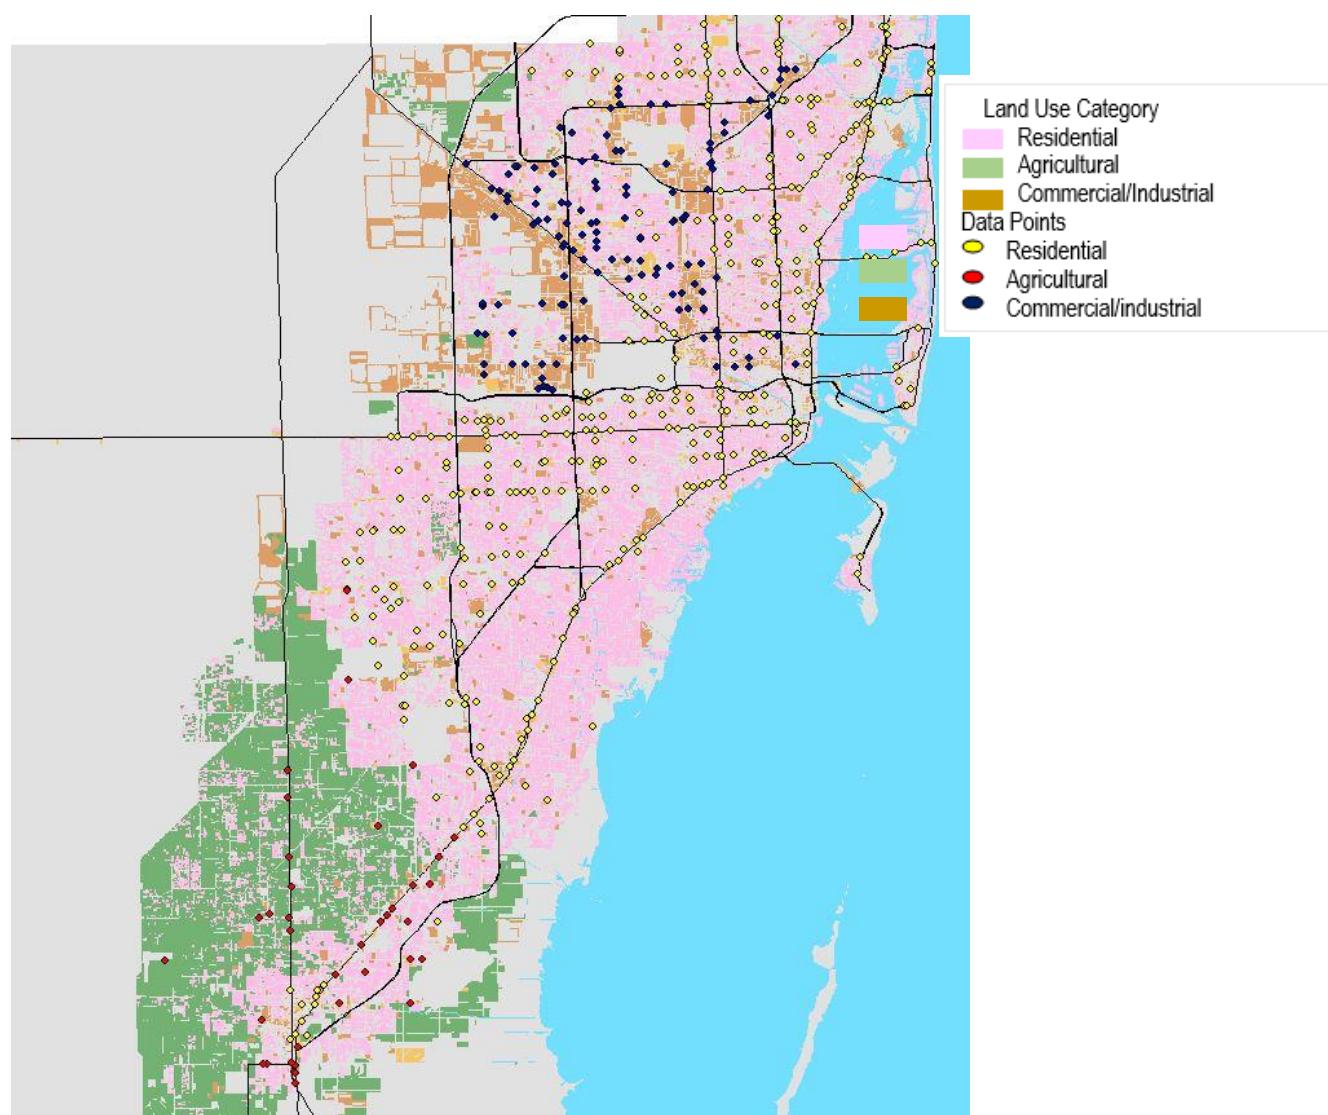

Figure 11: Miami-Dade County Residential, Agricultural and Commercial-Industrial Land Use Map.

(Developed from Miami-Dade County Open Data Hub-Land Use Symbology Data Miami-Dade County, Florida MD Publisher)

<https://gis-mdc.opendata.arcgis.com/maps/land-use-symbology-view>

## Background Concentrations of Metals in Groundwater-Miami-Dade County

The population distributions were indicated as being significantly different for the land use categories for the three metals evaluated. There was no indication of a statistically significant difference between the median aluminum concentrations for the land use categories evaluated as represented in Figure 12a. In the case of iron, the median concentration in primarily agricultural areas was significantly different and lower than for industrial and residential areas while for manganese the median concentration in industrial areas was significantly different and higher than for areas with residential and agricultural land uses. Figures 12b and 12c.

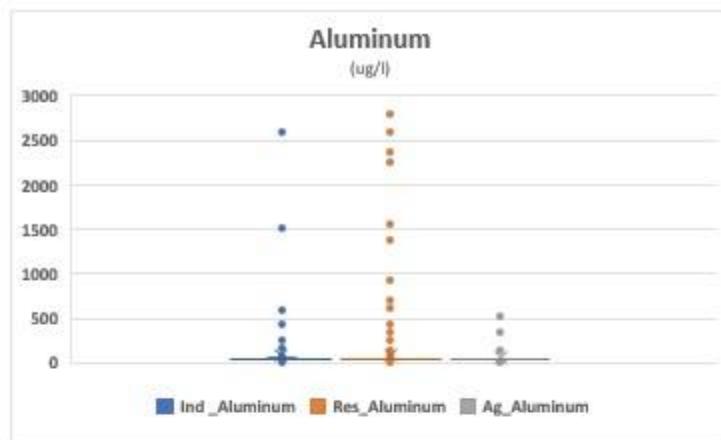

Figure 12a

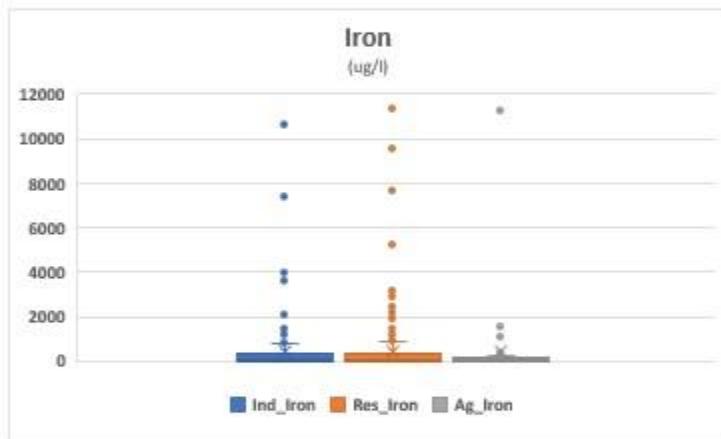

Figure 12b

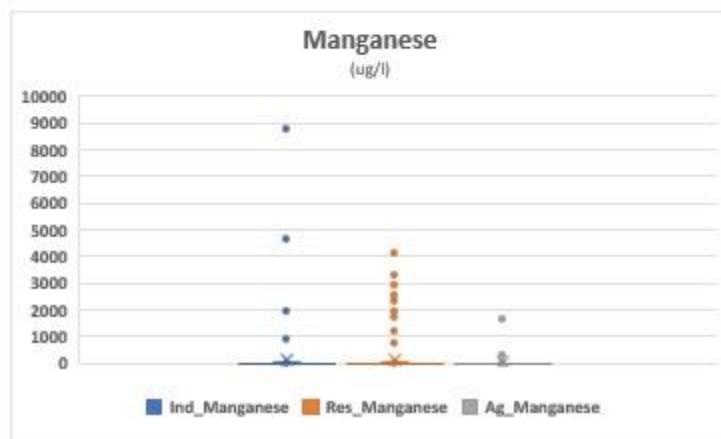

Figure 12c

## Background Concentrations of Metals in Groundwater-Miami-Dade County

### Consistency with DERM's Water Quality Monitoring Program

Aluminum, iron, and manganese data from the shallow wells in the Ambient Groundwater Quality Monitoring Program (AGWQP) for the period 2010 to 2021 was evaluated against the data from the synoptic groundwater sampling project. For aluminum and manganese both the median concentrations and population distributions indicated statistically significant differences. In the case of iron while the null hypothesis of equal medians was not rejected (Mann-Whitney W-test: 95% confidence level) there was a significant difference in the population distributions (Kolmogorov-Smirnov Test). Overall, the concentrations as indicated by central tendency descriptors were higher for the synoptic sampling project compared to the data set from the AGWQMP long-term monitoring. Figure 13. The disproportion in the size of the dataset for wells at equivalent depths, for the AGQMP versus the synoptic sampling dataset, n=71 and n=551, respectively, may have resulted in statistical biases.

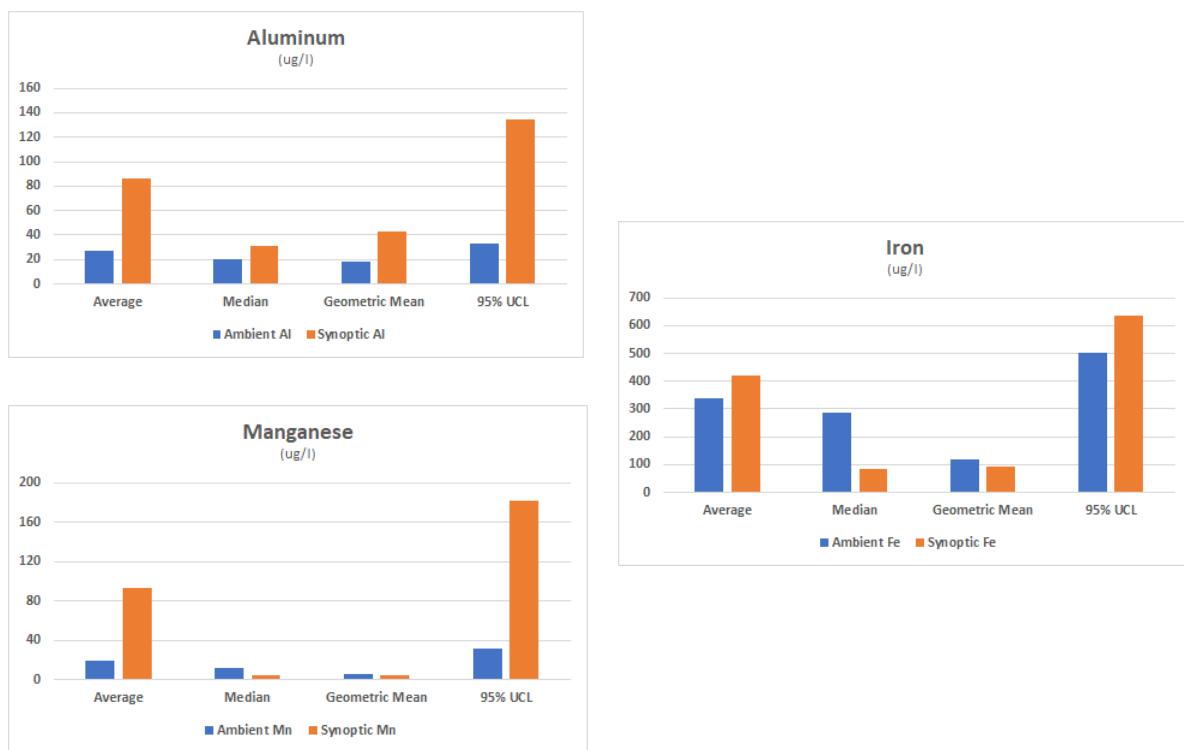

Figure 13: Aluminum, Iron and Manganese-AGWMP vs Synoptic Project-Central Tendency Descriptors

### Background Concentration of Iron in Miami-Dade County

Iron is the predominant metal documented in groundwater during this study and as such warranted further analysis to attempt to understand its distribution and variability. Consistent with the findings of Parker et al., (USGS 1955) and Schroeder et al., (USGS 1958) dramatic variation in iron concentrations were observed in monitoring wells within short distances of each other.

A 2005 study by Miami-Dade County, involving groundwater data from a one-time sampling event at 62 preexisting shallow wells in Miami-Dade County, yielded a countywide background concentration for iron of 706 µg/l based on the Minimum Unbiased Estimator of the Mean

## Background Concentrations of Metals in Groundwater-Miami-Dade County

(DERM 2005). Since its publication in 2005, this background concentration has been utilized as an appropriate cleanup endpoint on a case-by-case basis at site with groundwater iron contamination. The synoptic sampling data was compared to the 2005 concentrations to evaluate for consistency in the two datasets. Twenty three of the 62 locations sampled in 2005 were resampled for the synoptic project; in 65 percent of the cases the synoptic project reported reduced concentrations relative to the 2005 study. Statistically the populations are significantly different both for concentrations and population distribution as seen in Figure 14. The calculated MVUE for the current study relative to the 2005 study is 628 µg/l vs 706 µg/l with a combined MVUE of 664 µg/l.

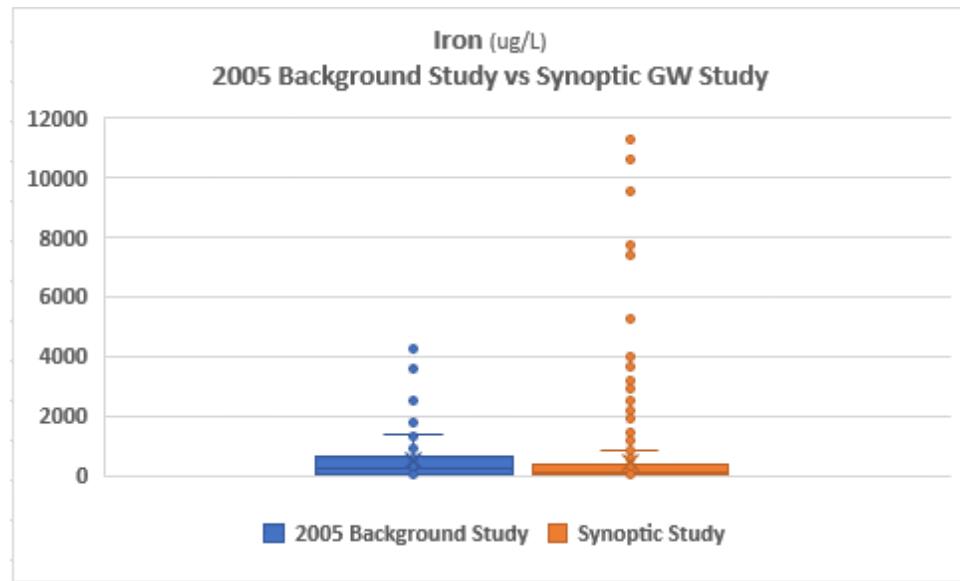

Figure 14: 2005 Iron Background Study vs Iron Concentration for Synoptic Study

## **Conclusion**

Background concentrations of metals in shallow groundwater in Miami-Dade County is unremarkable. Over 70 percent of the samples obtained during this study were reported at concentrations below detection limit. Four metals, aluminum, iron, manganese, and arsenic were detected at concentrations above their respective GCTL (percentages). The data for iron and to a lesser extent aluminum indicated some spatial variability along a north-south transect with higher concentrations documented in the north. Iron was the predominant groundwater contaminant. Iron is regulated based on aesthetic considerations and as such is a secondary standard. The occurrence and distribution of metals in groundwater was poorly to moderately correlated with groundwater geochemistry for aluminum, iron, and manganese.

## **Limitations of Study**

The interpretation of the study's findings was limited by the absence of essential groundwater geochemistry data such as redox potential, organic matter, TDS, sulphate, and total and dissolved organic carbon. These geochemical properties, which can have profound influence on metal dissolution, transport, and spatial distribution, were not measured during this study. Additionally, the data provided represents a one-time dry season only sampling events, and as such does not account for potential temporal variations and seasonality in groundwater quality .

## **Evaluating Background Concentrations**

Trace metals and especially metals that are abundant in the earth's crust such as aluminum and iron are frequently present in dissolved form in shallow groundwater at concentrations above the GCTL because of natural process unrelated to site discharges. Section 24-44(2)(f)(i) of the Code of Miami-Dade County allows that the GCTL may be superseded by background concentrations based on a naturally occurring background study approved by DERM.

The data provided herein is a resource and informational tool that may be utilized by environmental professionals during the initial site screening for site rehabilitation. The data may be utilized to determine the likelihood of potential contributions from naturally occurring background concentrations in a particular geographical locale. While a properly designed site-specific background may utilize and incorporate, as applicable and appropriate, data obtained in the general locale of the property under investigation, the information presented herein is not intended to be used as a surrogate for conducting a site-specific study. Further, the data should not be construed as default alternative cleanup target levels.

Environmental practitioners/professionals should utilize the concentration distribution of the data provided (as appropriate and applicable) for each chemical in conjunction with site specific information including, but not limited to; current and historical land use, site conditions, discharge history, onsite contaminant distribution, adjacent impacted or contaminated sites with relevant groundwater data, supplemental site-specific background data, along with professional judgement to drive site rehabilitation strategies.

Guidance for designing a proper site-specific background study and for appropriately comparing site concentrations against background concentrations are provided in DERM's Assessment and Remediation Guidance document available for download at <https://www.miamidade.gov/environment/library/instructions/risk-based-corrective-action.pdf> and also the Florida Department of Environmental Protection's guidance document at [https://floridadep.gov/sites/default/files/7-GroundwaterBackgroundGuidance2013\\_0.pdf](https://floridadep.gov/sites/default/files/7-GroundwaterBackgroundGuidance2013_0.pdf).

The data presented in this report (tables, copies of laboratory analytical reports) is available via Miami-Dade County DERM's electronic database at HWR-1207 available at [Supporting Data-Background Concentrations of Metals – Miami-Dade County.](#)

## **Acknowledgement**

MDC DERM wishes to acknowledge Arcadis's contribution to this project under contract with and on behalf of Miami-Dade County. Field work, initial data compilation and preliminary report development (Miami-Dade County Synoptic Groundwater Analysis Report Miami, Florida September 2020- (HWR-1207)) were conducted by Arcadis. The data evaluation and conclusions presented in this report builds on the work conducted by Arcadis.

In addition, we would like to acknowledge the extraordinary support provided by the MDC DERM-EMRD Laboratory staff without which this report would not have been possible.
