EXECUTIVE SUMMARY

Several studies have documented soil and groundwater contamination nationally as a result of agrichemicals used in golf course turf maintenance. At the state and local level, environmental resources degradation attributable to golf course maintenance has also been documented. This report presents the results of a study, co-sponsored by the Miami-Dade County Department of Environmental Resources Management (DERM) and the Florida Department of Agriculture and Consumer Services (FDACS). The study quantifies the environmental impact of agrichemical turf maintenance at five golf courses in Miami-Dade County, Florida.

Five publicly owned golf courses participated in the study. Groundwater, surface water and sediments were sampled quarterly at the participating golf courses in 1997; however, surface water and sediments were not sampled during the first quarter. Soil profile samples were obtained during monitoring well installation and surficial soil samples were obtained during the quarterly sampling events thereafter. Groundwater and surface water were sampled and analyzed for a total of fifty-one pesticide residues, arsenic, nitrates, and phosphates. Soil and sediments were sampled for arsenic.

Arsenic was detected in all environmental media at all the golf courses. Arsenic was ubiquitous in golf course soils: seventy-five percent (75%) of soil borings and surficial soil samples exceeded the Florida residential soil cleanup target level (CTL); sixty-two percent (62%) exceeded the industrial CTL. Highest soil arsenic concentrations occurred in surficial soils but overall soil arsenic concentrations were not correlated with depth in the soil profile. There were no statistically significant differences in soil core or surficial soil arsenic concentration either between golf courses or between golf course areas (greens, tees, fairways and mix/load).

Arsenic was detected in eighty-five percent (85%) of shallow (7-12 ft) groundwater samples. Concentrations exceeded the current maximum contaminant level (MCL) of 50 ug/L in thirty – two percent (32%) of the samples while seventy-seven percent (77%) exceeded 10 ug/L, the revised arsenic MCL that is scheduled to take effect in 2006 (2006 MCL). The highest groundwater arsenic concentrations occurred in the samples obtained from mix/load sites. Among the play areas (tees, greens and fairways), tee sites had the highest arsenic concentrations in shallow groundwater and represented a statistically different population from greens and fairways.

Arsenic was detected in deeper (21-28 ft) groundwater in thirty-seven percent (37%) of the samples; however, the MCL was not exceeded. The 2006 MCL was exceeded in twelve percent (12%) of the samples.

Surface water samples were obtained from four golf course ponds. Arsenic was detected in eighty-three percent (83%) of the surface water samples; none of the samples exceeded the surface water cleanup target level (50 ug/L).

In addition to arsenic, nine pesticide residues (chlorothalonil, chlorpyrifos methyl, dieldrin, metribuzin, metalaxyl, prodiamine, chlorodane, heptachlor epoxide and oxadiazon), were detected in shallow groundwater. However, only five pesticides were detected at concentrations above the practical quantitation limits (PQL) of the relevant analytical method and only one pesticide, dieldrin occurred at concentrations exceeding the MCL. Pesticides were not detected at levels above the PQL in deeper groundwater samples. The occurrence of dieldrin and chlorpyrifos methyl in groundwater at golf courses cannot be attributed to current turf management activities. One pesticide, atrazine was detected in groundwater in one background well; concentrations did not exceed the CTL. Four pesticide residues, fonofos, atrazine, oxadiazon and ethoprop were detected in surface water from golf course ponds. Ethoprop (0.315 ug/L) and fonofos (0.095 ug/L) exceeded the freshwater surface water cleanup target level.

Nitrate nitrogen was detected in seventy-six percent (76%) of shallow groundwater samples and exceeded the MCL of 10 mg/l in twenty-one percent (21%) of the samples. Nitrates were detected most frequently and highest concentrations were found in groundwater at mix/load sites. Nitrates were also detected in surface water.

Data from this study indicates that golf course soils are impacted by arsenic. In groundwater, elevated arsenic concentrations are predominantly restricted to samples near the top of the saturated zone. With the implementation of the 2006 MCL, the observed arsenic concentration in shallow groundwater will take on greater regulatory significance. Arsenical pesticides used in routine turf management are suspected to contribute to elevated arsenic levels at golf courses.

INTRODUCTION

With approximately 1000 golf courses occupying some 10,600 acres (Balogh and Walker, 1992), Florida rivals California as the golf course capital of the United States. Golf is an eighteen billion dollar per year industry in the United States (USGA) with over 25 million golfers (National Golf Foundation). The increasing popularity of the game has attracted public scrutiny, and in some cases criticism, regarding the potential environmental consequences of golf course construction and management. The potential for agrichemical usage at golf courses to cause environmental contamination is of special concern in areas such as Miami-Dade County, where groundwater, the sole source of drinking water, is three to ten feet below land surface in most urban areas.

BACKGROUND

Routine, permit-related inspections conducted by the Department of Environmental Resources Management (DERM) staff at ten golf courses in Miami-Dade County between 1994 and 1996 documented violations of soil cleanup target levels (CTL) and water quality standards. The most common contaminant was arsenic. Documented incidents were generally attributed to spills and inappropriate mix/loading practices and occurred most commonly at mix/load sites where pesticides and fertilizer mixtures are prepared and loaded into application equipment. Based on the evidence of agrichemical impact to the environment at mix/load sites, there was concern that in the play areas (greens, tees and fairways) where agrichemicals are routinely applied, these agrichemicals also have the potential to accumulate to concentrations that exceed environmental standards. The validity of this concern was reinforced by data from golf courses in north and central Florida that documents agrichemical impacts to groundwater (Swancar 1996) at the participating golf courses.

To evaluate the impact of agrichemical usage on the soil and water resources at golf courses in Miami-Dade County, the DERM and the Florida Department of Agriculture and Consumer Services (FDACS) co-sponsored the current study. DERM staff oversaw the project, while FDACS provided logistical support and technical review.

PURPOSE AND SCOPE

The objectives of the study were to determine the following:

1. The degree and extent to which groundwater, surface water, soil, and sediment quality at golf courses in Miami-Dade County are impacted by agrichemicals used in turf management.
2. The relationships, if any, between the concentrations of agrichemicals detected in environmental samples and the pattern of use of those agrichemicals with respect to golf course greens, tees, fairways, and mix/load areas.

PREVIOUS STUDIES

In contrast to agricultural practices, relatively few studies have focused on the relationship between turf management practices and water quality at golf courses. Wan (1994) and Miles (1990) documented trace levels of pesticides in runoff from golf courses. Cohen, et al. (1990) sampled nineteen monitoring wells at four Cape Cod (Massachusetts) golf courses overlying a shallow, highly transmissive aquifer for seventeen pesticides (arsenic was not investigated) and other related turf management chemicals. Eight pesticide residues were detected in groundwater samples with the most frequent detections associated with greens and tees. Only chlordane was found in concentrations exceeding the MCL of 2 ug/L. Nitrate-nitrogen was detected but at concentrations below the MCL of 10 mg/l. Only chlordane and heptachlor epoxide were detected in soils from the study area.

Between 1991 and 1997, the US Golf Association (USGA) funded several university studies to evaluate the environmental fate of seventeen pesticides and various fertilizer formulations used at golf courses. The research indicated that, when properly applied, leaching is minimal because the turf/soil ecosystem enhances pesticide adsorption and degradation and therefore reduces the amount of chemical available for leaching. Surface runoff from treated areas was identified as being potentially significant, especially in areas of high rainfall

The US Geological Survey (Swancar 1996) studied the effect of turf management practices and irrigation with reclaimed water at nine golf courses in Florida. Samples were collected from groundwater wells, golf course ponds, irrigation water, effluent ponds, and effluent from sewage treatment plants. Analyses included forty-one pesticides, nutrients, major ions, and trace elements. Pesticide residues were detected in groundwater at seven of the nine golf courses and in fifty-two percent (52%) of the groundwater samples. Relatively few pesticides occurred at concentrations exceeding regulatory levels; however, arsenic, bentazon, and acephate were detected in groundwater at concentrations above the MCL or guidance concentration. Arsenic was detected above the MCL in 8% of the samples but 58% exceeded the 2006 MCL. Pesticides were detected in golf course ponds at trace levels. Although nitrates were detected in groundwater, few samples exceeded the MCL.

ENVIRONMENTAL SETTING OF MIAMI-DADE COUNTY

Miami-Dade County is located at the southeastern tip of the Florida peninsula (Figure 1). It is bordered by the Everglades National Park (ENP) on the west, by Broward County on the north, the Florida Keys (Monroe County) and Florida Bay on the south, and the Biscayne Bay National Park and the Atlantic Ocean on the east.

Prior to development, the county consisted of a vast expanse of wetlands extending eastward to within a few miles of the coastline. Along the coast was a fringe of sandy flatlands, coastal marshes, and mangrove swamps (Fish and Stewart, 1991). Many decades ago, canals were dug across south Florida to drain swampy areas and to provide flood protection for the resulting urban and farmed areas. Today the western portion of the county remains as protected wetlands. Development is restricted to 1,000 square miles along the eastern half of the county (Figure 2)

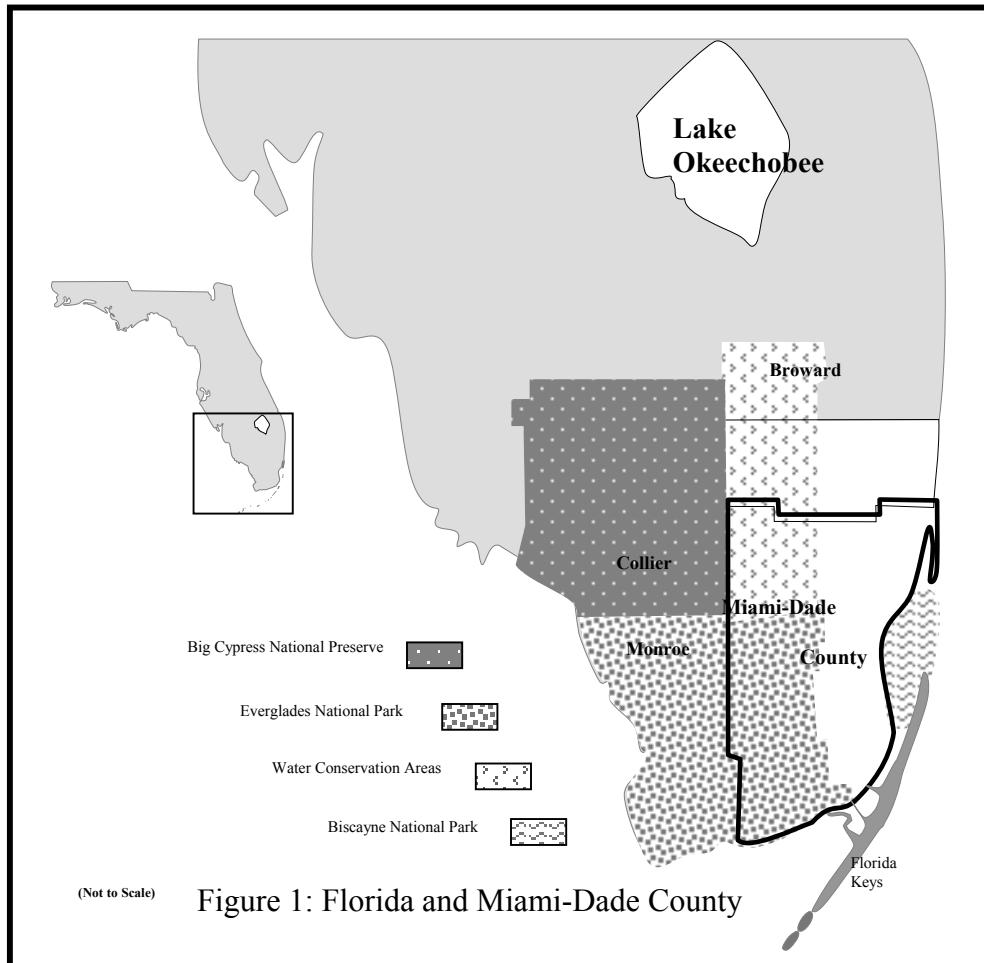

Figure 1: Florida and Miami-Dade County

Underlying Miami-Dade County is the Biscayne Aquifer. In 1979, the EPA declared the Biscayne Aquifer a “sole source” aquifer because it is the only source of potable water for this area. This aquifer is one of the most permeable in the world (Parker, 1955) and because it is overlain by only a few inches to a few feet of surficial soils, it is vulnerable to contamination. The water table averages between 3-10 feet below ground surface in the developed areas of the county. In the undeveloped western portions of the county, groundwater flow is generally south, southwesterly from the water conservation areas and the ENP into Florida Bay. In the developed eastern portion, the groundwater flows in a general east-southeasterly direction, unless subjected to anthropogenic influences, and ultimately discharges into Biscayne Bay (Figure 3).

The Biscayne Aquifer varies in thickness from about 20 feet near the western border of the county to between 100 and 200 feet near the coast (Randell and Katz 1991). Approximately 500 feet of dense and impermeable deposits (the Floridan aquiclude) lie below the Biscayne Aquifer. Below these deposits is the Floridan aquifer (Fish and Stewart 1991), containing brackish, non-potable water (Figure 4).

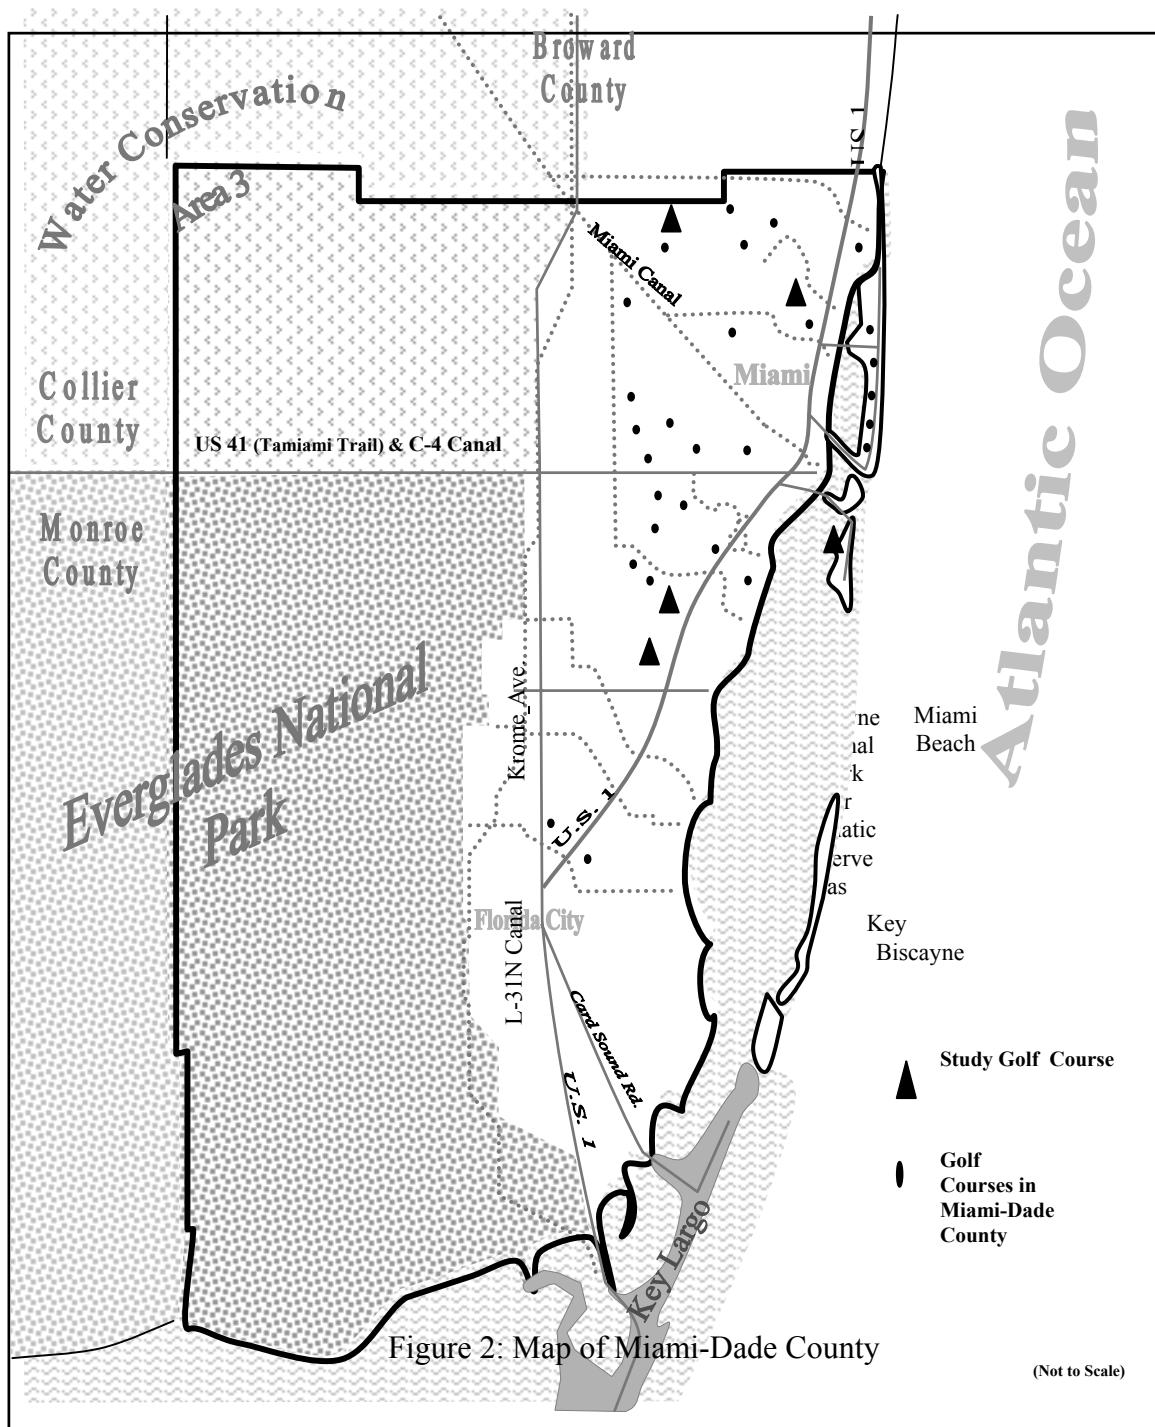

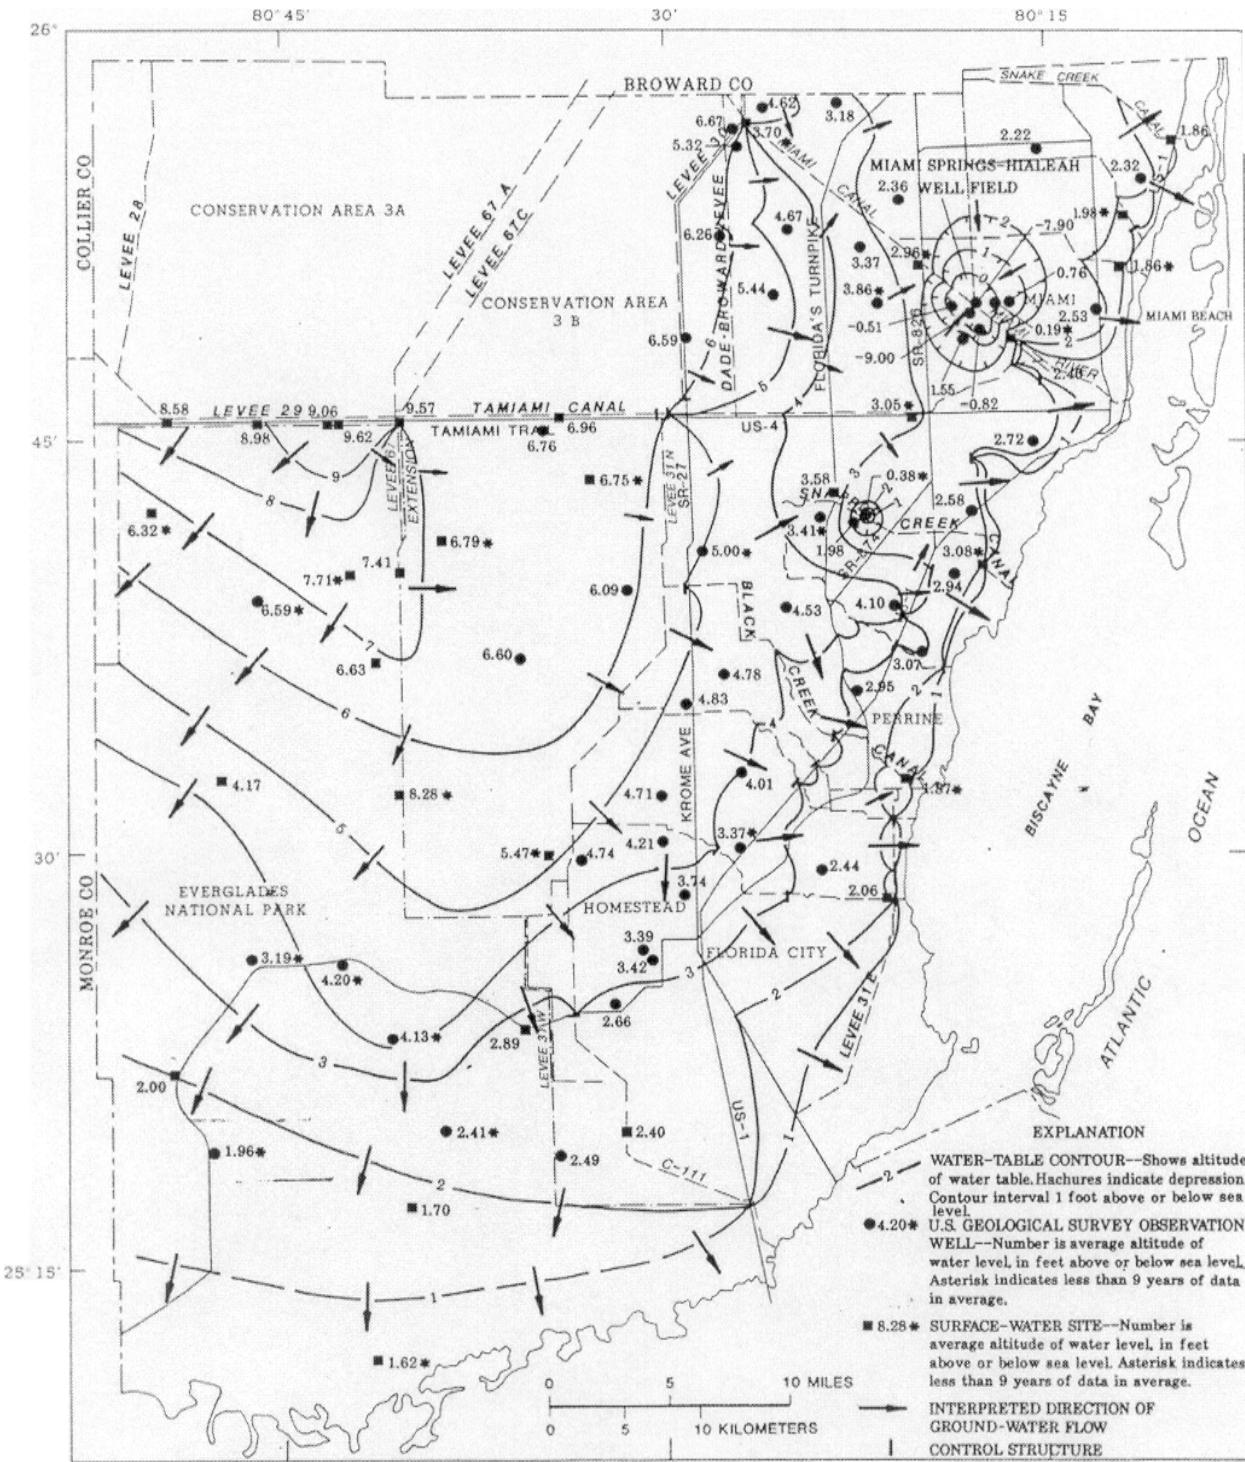

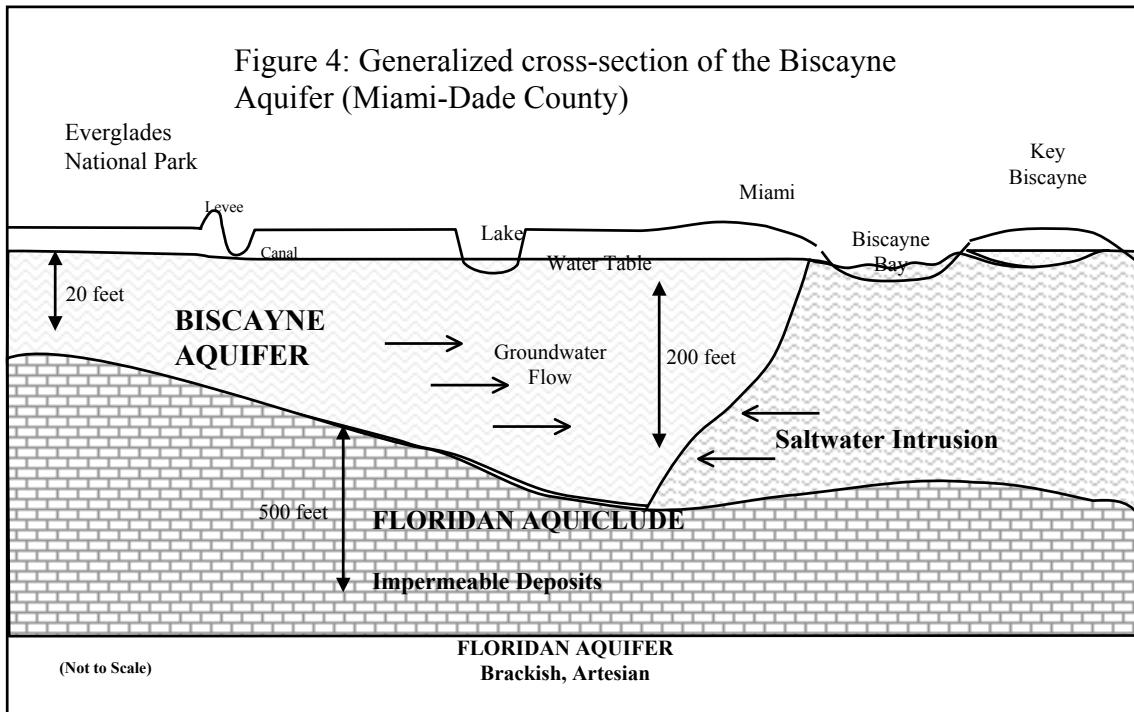

Figure 3: Interpretive groundwater flow direction for Miami-Dade County (Fish and Stewart, 1991)

STUDY SITE SELECTION

Five of six county-owned municipal golf courses were selected to participate in this study: Briar Bay Golf Course, Golf Club of Miami, Greynolds Park Golf Course, Key Biscayne Golf Course (also known as Crandon Golf Course), and Palmetto Golf Club. The limitations of the study precluded random selection of the participating courses from the thirty-three active golf courses in Miami-Dade County. Golf course selection was based exclusively on logistic and accessibility considerations. Therefore, there may be limitations to applying conclusions from the study to all municipal golf courses in Miami-Dade County or to private golf courses with different management practices.

The five golf courses are representative of golf courses countywide in terms of age, design, and size. Average acreage for the participating golf courses was 130 acres for eighteen hole courses and forty-five acres for nine hole courses, consistent with a county-wide average of 133 and forty-eight acres for eighteen and nine holes, respectively (DERM files). The average age for golf courses countywide is thirty-six years, similar to the average of thirty-five years for the golf courses studied (DERM files). Although environmental factors such as soil type, geology, and physical features were not considered during golf course selection, the selected courses exhibited diversity with respect to these parameters. Soil encountered in the study ranged from urban fill to fine sands overlaying bedrock that varies from porous oolitic limestone to hard, fossilized formations. Groundwater was encountered at 3-8 ft below land surface and exhibited specific conductivity values representative of saline to freshwater conditions. Detailed site-specific descriptions are provided in Appendix A.

The study design recognized that the selected courses were probably not representative of golf courses countywide in terms of pesticide usage. Due to agrichemical management practices, public golf courses tend to use less pesticide than private golf courses. Information from a pesticide use survey of eight golf courses (DERM, 1996) indicated an average of 104 gallons and 1630 lbs. of pesticides (product weight) used per year at public golf courses compared with 204 gallons and 3656 lbs. at private golf courses. However, a review of pesticide inventories obtained from private and public golf courses between 1994 and 1996 (DERM records) indicated that although golf courses may differ in terms of quantities used, the active ingredients used do not differ significantly.

ASSESSMENT AND MONITORING PROGRAM DESIGN

The study was designed to evaluate the degree and extent of environmental impact from agrichemical usage at golf courses and to determine whether or not observed impacts were consistent across all golf courses studied or among areas at the golf courses with differently management regimes with respect to agrichemical usage. To this end the groundwater monitoring sites were established adjacent to different play areas (fairways, greens, tees), and agrichemical mix/load areas at the participating golf courses. Soils, surface water and sediments were sampled from areas selected for monitoring.

Six groundwater-monitoring wells were installed at each of the participating golf courses during February 1997. The wells were installed as paired wells, with three pairs (clusters) at each golf course. At each golf course two of the well clusters were located adjacent to either greens, tees or fairways; the remaining cluster was located within or adjacent to the mix/load site. At the Golf Club of Miami and the Key Biscayne Golf Course, to avoid nearby underground or overhead utility conduits, the mix/load wells were installed at distances of 200 and 82 feet away from the mix/load sites, respectively. Monitoring wells were sited to avoid low areas that receive runoff during normal rainfall events. In addition, at Key Biscayne Golf Course, because the southern portions of the property existed as a municipal dump prior to establishment of the golf course, care was taken not to locate sampling points within the boundaries of the former dump. The distribution of monitoring well sites for each of the participating golf courses is shown in Table 1. Site maps and monitoring locations for each golf course are provided in Appendix B.

Table 1: Distribution of Monitoring Wells by Type of Golf Course Area

	Briar Bay	Golf Club	Greynolds	Key Biscayne	Palmetto
Mix/load	X	X	X	X	X
Fairway	XX			X	X
Green		X	X		X
Tee		X	X	X	

Each well cluster consisted of one shallow and one deeper well. The shallow well was designed to provide samples from the soil water interface and was constructed with five feet of screening that extended two feet above and three feet into the water table. The deep well consisted of two feet of screening placed at approximately 20 feet below the water table.

Three pre-existing monitoring wells, selected from an Ambient Water Quality Monitoring (AWQM) network were sampled concurrently with the golf course wells to provide information on current offsite background concentrations of the contaminant of concern (COC). Wells in the AWQM network are used by various environmental regulatory agencies including DERM, to provide ambient water quality and water level information for Miami-Dade County. The background wells selected represented the closest available background wells to the golf course participating in the study. The data from the three selected wells were combined with historical data from the network to provide current and historic background information for data analysis and discussion. A total of fifty-one pesticide residues, arsenic, nitrates, and phosphates were examined in the study (Table 2).

The 30 golf course monitoring wells along with the background wells were sampled four times during 1997 (February, May, August, and November). During each sampling event, a Hydrolab H2O® Multiprobe with Hydrolab Surveyor® 3 Display Logger was used to measure field parameters: temperature, pH, specific conductivity, redox potential, dissolved oxygen and salinity. In addition to the field parameters, groundwater was sampled and analyzed for the COC indicated in Table 2.

During monitoring well installation (February 1997), 43 soil core samples were collected from the deeper monitoring well sites and analyzed to evaluate the vertical distribution of total arsenic in the vadose zone. Soil samples were taken at two-foot intervals down to the soil/water interface.

During the May, August, and November sampling events, a total of 31 composite surficial soil samples (0-1 ft deep) were obtained from targeted playing areas and analyzed for arsenic. Each composite sample consisted of fifteen individual sub-samples taken ten feet apart around the inside perimeter of the play area, in the case of greens and tees. In the case of fairways, the sub-samples were collected from the side of the fairway closest to the monitoring well.

Four of the five participating golf courses have ponds. At each of these golf courses, one pond was selected for surface water and sediment sampling. Each selected pond was located such that it would receive surficial storm water runoff from an area being monitored for groundwater quality. The ponds were located within 100 to 160 feet of a monitoring well and were sampled during May, August, and November of 1997

As an addendum to the study, in January 1998, the Florida Department of Health (FDOH) sampled nine private drinking water wells near Briar Bay and Palmetto golf courses. These are the only courses in the study that had homes with documented potable wells located within a quarter to half a mile radius of the golf courses. The wells were sampled for arsenic and nutrients. The FDEP laboratory analyzed the samples. In addition, all the golf course wells were re-sampled in March 1999 to determine if arsenic levels had changed significantly from the 1997 levels.

SAMPLING METHODOLOGY

Field activities were performed in accordance with a DERM approved project specific quality assurance plan.

1. Groundwater

Except in the case of the mix/load site at Greynolds Park Golf Course and Palmetto Golf Course, wells were purged using a gasoline powered centrifugal pump equipped with one-inch diameter PCV tubing fitted with a backflow device on the intake end. The mix/load wells at Greynolds Park Golf Course and Palmetto Golf Course were purged using a 2-inch diameter TeflonTM bailer. A total of five well volumes were purged prior to sampling. Groundwater was analyzed for pesticides, arsenic, nitrates, and phosphates.

Groundwater samples were collected using a peristaltic pump and TeflonTM tubing. For pesticide sampling, an inline Teflon trap was used. The sampling sequence was pesticides, metals then nutrients. Pre-cleaned tubing was used for each well. Samples were preserved in the field as required, packed on ice, placed in a secure cooler and transported to the laboratory.

Field measurements were obtained from each well using a HydrolabTM. The measurements were obtained subsequent to sampling using a continuous-flow sampling chamber. Field measurements included temperature, pH, salinity, redox-potential, conductivity, and dissolved oxygen.

2. Surface Water

Surface water samples from freshwater ponds were collected in May, August, and November 1997. Samples were obtained via boat from the center of the pond. These samples were collected from a depth of approximately one meter below surface and were obtained using a pre-cleaned NiskinTM sampler. Samples were analyzed for pesticides, arsenic, and nutrients.

3. Sediment

Sediment samples were obtained as grab samples using a stainless steel Ponar grab sampler. Sediment samples were collected during the May, August and November events. The samples were obtained from the center of the pond in the approximate area from which the surface water sample was collected. Sediments were analyzed for arsenic.

4. Soil

During monitoring well installation (February 1997), soil core samples were obtained via split spoon from two- foot intervals down to the soil/groundwater interface. During the May, August, and November sampling events, surficial (0-1 ft) soil samples were obtained from areas being monitored. The samples were collected as composite samples with each composite consisting of 15 sub-samples obtained approximately ten feet apart around the inside perimeter of the green,

tee, fairway or mix/load site. The sub-samples were mixed in a stainless steel tray to produce the composite sample that was subsequently submitted for arsenic analysis.

5. Quality Assurance Samples

Quality assurance samples obtained included equipment blanks and field duplicates. No field blanks were obtained since the project did not involve sampling for volatile organics. For groundwater and surface water samples, one field duplicate was obtained for every ten samples (10%) for each parameter. Field duplicates were collected, stored, and transported in exactly the same manner as the other samples. Since field duplicates were collected to assess the precision of a sample set, the results of these samples are not reported here. Field duplicates were used during the process of data validation to determine data acceptability. Except in the case of arsenic, if the relative percentage difference (rp_d) between a sample and its duplicate exceeded twenty percent, the data were rejected. In the case of arsenic, the rp_d exceeded 20 percent in three samples; however, because of the potential for inherent variability with metal samples, these three data points were qualified but not rejected. No field duplicates were taken for soil or sediment samples.

Equipment blanks were obtained at the start of each sampling event and at a rate of one blank for every twenty samples thereafter. Blanks were obtained as a quality assurance measure to assess the adequacy of field and laboratory cleaning procedures.

ANALYTICAL METHODS

EPA Method 614 was used to analyze the samples for organo-nitrogen and organo-phosphate pesticides while EPA Method 608 was used for chlorinated pesticides and PCBs. The FDEP laboratory analyzed all pesticide samples.

The active ingredient in the arsenical herbicides used at golf courses is MSMA, an arsenic compound. There is no EPA approved analytical methodology to test for MSMA; therefore, the samples were analyzed for arsenic. Groundwater and surface water samples were analyzed using EPA Method 200.7. Soil and sediments were analyzed using EPA Method 7060; because the analytical methods used tested for arsenic and not for MSMA specifically, arsenic from other sources may also have been measured. The FDEP laboratory conducted all analyses for arsenic in water while the DERM laboratory conducted the analyses for soil and sediments.

Nitrates and phosphates samples obtained during the first groundwater sampling event were analyzed by DERM laboratory using EPA Methods 353.2 and 365.1, respectively. Post, Buckley, Schuh, and Jernigan (PBS&J) laboratory performed all subsequent nitrate and phosphate analyses using EPA Method 353.2 and EPA Method 365.4, respectively.

STATISTICAL METHODS

Statistical analyses were performed using SPSS™ Students Version 8.0 Software for Windows and SigmaStat Version 2.03 for Windows. Preliminary data analysis using the Kolmogorov-

Smirnov test indicated that some of the data sets did not fit either a normal or log-normal distribution, and as such, all analyses were performed using non-parametric statistics. Non-parametric methods are independent of the shape of the sample distribution and use ranked data instead of the actual raw data. For the non-parametric tests, the data is ordered and then assigned ranks. The values of the assigned ranks are used in the analysis.

Based on the indication that the data did not fit a normal distribution, the median is the central tendency statistic used in discussions; however, the mean and the 95% UCL are also presented in the tables. The 95% UCL is calculated using Hall's non-parametric bootstrap-t method (Singh et al, 1997).

In the cases where there was available environmental data on background concentrations of the contaminants of concern (COC), the study data was compared to the background data to detect statistically significant differences. In addition, based on the assumption that concentrations of a specific COC might be influenced by variables not controlled in the study design (soil type, geology, geochemistry, etc), the data was analyzed to detect significant differences in COC concentrations between the five golf courses. The data was also analyzed for relationships between environmental concentrations of the COC as a function of agrichemical usage in the different managed areas: greens, tees, fairways, and mix/load areas. For comparisons between golf courses, the data points from each golf course were pooled and each golf course was treated as a sample population. To examine differences among golf course managed areas, data from each of the four areas was combined into four sample populations.

The Mann-Whitney, Kruskal-Wallis, Dunn Pairwise Multiple Comparison Procedure and Tukey-Type Multiple Comparison Procedure were the main statistical tests used. The Mann-Whitney test is the non-parametric analogue to the two-sample t test and is used to test for differences between two populations. The Kruskal-Wallis test is the non-parametric alternative to a one-way ANOVA and is used to test for differences among three or more populations. The Kruskal-Wallis test indicates when the test populations differ but is incapable of indicating which population is different. Therefore, for multiple comparison testing, whenever a difference was indicated by the Kruskal-Wallis statistic, the data was then analyzed using the Dunn Pairwise or Tukey-Type Multiple Comparison Procedure to isolate the population(s) that differ.

The Spearman Ranked Correlation (ρ) was used to evaluate linear relationships between variables of interest. Except as otherwise noted, a 0.05 significance level was used for hypothesis testing. In cases where over 80 percent of the samples were below the method detection limit, no statistical comparisons were performed and only the population descriptors are presented. In cases where the number of non-detect measurements was less than 20 percent, a value of half the detection limit was assigned to values reported as BDL (Gibbons, 1994).

RESULTS AND DISCUSSION

Arsenic

Unlike most pesticide ingredients, arsenic occurs naturally in many soils. Nationally, high background arsenic levels have been documented in soils from the western states; this is in contrast to soils from the southeastern areas of the nation where, typically, only trace levels are detected. A recent study that examined thirty-eight soil samples obtained from undisturbed areas of Miami-Dade County indicates that background arsenic concentrations in surficial soils range from <0.2 to 3.89 mg/kg (DERM internal memo, 2002). Arsenic may also be present in soils due to industrial contamination, past agricultural practices, and current application of arsenic containing fertilizer and soil amendments, or other sources such as fill material.

At the golf courses in this study, arsenic is routinely applied as MSMA. A total of twenty-eight herbicide brands containing MSMA as the active ingredient were registered for use in the state of Florida at the time of the study. Based on current application rates for the two most popular formulations, golf courses can apply between 255 and 282 grams /1000sq ft/year of elemental arsenic applied as MSMA. Data from a pesticide use survey administered at nine golf courses in Miami-Dade County (DERM files) indicates that between 7 to 208 kilograms of elemental arsenic is applied per golf course annually.

Arsenic in Soil

Summary statistics for arsenic concentrations are presented in Table 3. Most of the soil samples collected during the study exceeded both the residential (0.8 mg/kg) and industrial (3.7 mg/kg) soil cleanup target level (CTL). In the case of the surficial soil samples, ninety-four percent (94%) exceeded the residential and eighty-seven percent (87%) exceeded the industrial soil CTL. The data indicates that the concentrations of arsenic in the surficial soils at the golf courses do not reflect naturally occurring background concentrations for Miami-Dade County. As previously referenced, background surficial soil arsenic concentrations ranges from <0.2 to 3.89 mg/kg (n=32) with a mean of 1.22 mg/kg calculated using the Minimum Variance Unbiased Estimator (MVUE) and an arithmetic mean of 1.05 mg/kg.

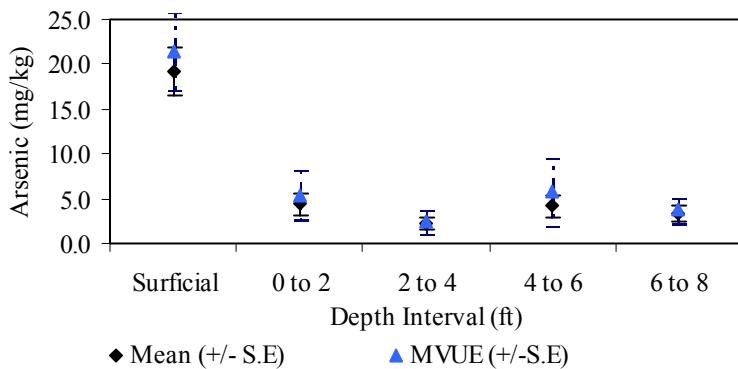

Arsenic concentration in the soil column samples obtained during monitoring well installation exceeded the residential and industrial soil CTL in sixty-two percent (62%) and forty-three percent (43%) of the cases, respectively. Although highest soil arsenic concentrations occurred in the 0-2 ft interval, overall arsenic concentrations were not correlated with depth (Figure 5a).

Table 3: Summary Statistics for Soil Arsenic Concentration (mg/kg)

	N	Median	Mean	95% UCL*	Min	Max
Soil Column	42	1.19	3.41	5.91	0.1	17.19
Surficial Soils	31	15.10	21.7	23.5	0.80	54.80
All Soils	73	5.6	10.09	17.21	0.1	54.80
Miami-Dade Background	32	0.9	1.05	1.55	0.1	3.89

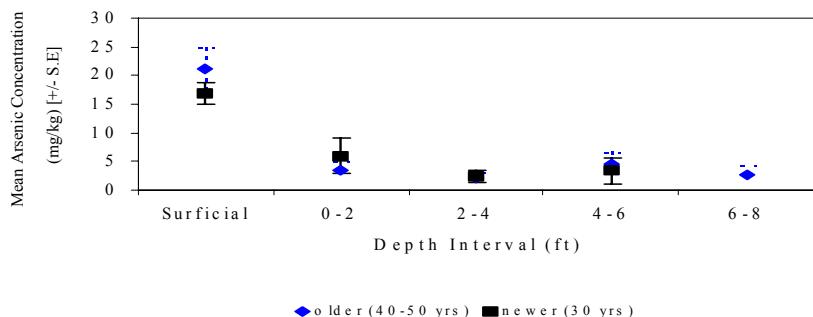

*Calculated using the Bootstrap t Method based on theory reported by Singh et al (1997). BDL are assigned a value of 0.1 mg/kg (1/2 the method detection limit).

Figure 5a: Mean Soil Arsenic Concentration

Arsenic concentrations were examined to determine if the distribution appeared to be influenced by the age of the golf course. Golf Club of Miami, Greynolds Park, and Palmetto Golf Course were constructed during the 1950s and early 1960s while Key Biscayne and Briar Bay Golf Course were constructed during the early 1970s. Although the range of golf course age was limited to relatively older courses, within the range encountered in the study, golf course age is not an influencing factor with respect to the distribution of mean arsenic concentrations in the soil column. Older and newer golf courses exhibited a similar distribution pattern and both mirrored the pattern observed for all golf courses combined (Figure 5b).

Figure 5b : M ean A rsenic C oncentration i n S o i l s : N ewer v e r s u s O l d e r G o l f C ourses

Arsenical pesticides such as lead and calcium arsenate were used extensively in agriculture prior to the 1980s when the EPA cancelled most registrations for agricultural applications; therefore, past agrichemical uses can result in elevated arsenic concentrations in the environment. Historical data indicates agriculture as the former land use at Palmetto Golf Course. Surficial soil arsenic data from Palmetto was compared with data (DERM files) from agricultural areas in Miami-Dade County ($n = 29$, mean = 7.79 mg/kg) to determine if the levels of arsenic in surficial soils at this golf course are artifact of previous agricultural use. Based on Mann Whitney analysis, arsenic concentrations at the golf course are higher than those typically found in agricultural soils in Miami-Dade County. Fill material, used in golf course renovation and reconstruction, has been suggested as one potential source of arsenic to the golf course.

environment. Arsenic concentrations in samples obtained from limestone quarries (DERM internal memo, 2002), which are the primary source of fill material used throughout the county, were examined to determine if fill materials could be introducing arsenic to the golf course environment. Arsenic was not detected in any of the quarry samples ($n = 22$, MDL = 0.2 mg/kg).

Arsenic in Groundwater

Shallow wells (7-12 feet)

Arsenic was detected in fourteen of the fifteen shallow groundwater wells with a median concentration of 27.50 ug/L. Approximately thirty-two percent (32%) of shallow groundwater samples exceeded the current MCL (50 ug/L) for arsenic in groundwater (Chapter 62-550, Florida Administrative Code) and approximately seventy-seven percent (77%) exceed the 2006 MCL of 10 ug/L (Table 4).

There were no statistically significant differences in shallow groundwater arsenic concentrations across the five golf courses. This suggests that the concentrations encountered are representative of municipal golf courses in Miami-Dade County and are independent of variables such as soil type, geology, and geochemistry. In addition, a comparison of shallow groundwater arsenic concentration between older and newer golf courses indicated no significant difference between these two populations; however, when the data from shallow wells are compared to background arsenic data, a significant difference is observed. This implies that arsenic concentrations in the shallow wells at golf courses, while being typical for the golf course environment, do not reflect background conditions.

Data collected from shallow wells during the follow up sampling event of March 1999 indicated increased arsenic concentration in shallow groundwater from four wells and decreased concentrations in two wells. However median arsenic concentration was not significantly different from the 1997 value.

Table 4: Summary Statistics for Arsenic in Shallow Groundwater

Golf Course	n	Arsenic Concentration (ug/L)					(#) and % of samples exceeding	
		Med	Mean	95% UCL	Min	Max	Current MCL 50ug/L	2006 MCL 10ug/L
Briar Bay	12	2.5	198.3	376.6	1.0	815	(5) 41.7%	(5) 41.7%
Palmetto	12	56.0	17.2	27.7	1.0	10.5	(1) 8.3%	(6) 50.0 %
Key Biscayne	12	14.0	74.1	138.2	14.0	392.0	(4) 33.3%	(12) 100%
Golf Club of Miami	12	30.0	49.0	74.7	12.0	123.0	(4) 33.3%	(12) 100%
Greynolds Park	12	30.0	76.5	128.8	10.0	243.0	(5) 41.7%	(11) 91.7%
Total	60	27.5	82.9	176.6	1.0	815.0	(19) 31.7%	(46) 76.6%
Background*	30	2.0	2.81	3.13	1.0	13.9	(0) 0 %	(1) 4.5%

Values reported as BDL are assigned the value of 1 ug/L (½ the method detection limit).

* Historical data from wells of similar depth (10-13 ft) in the AWQM network combined with data from the background wells sampled concurrently with the golf course wells.

Deeper Wells (21-28 feet)

There were no exceedences of the current arsenic MCL in groundwater from the deeper wells; however, approximately twelve percent (12%) of the samples exceed the 2006 MCL of 10 ug/L (Table 5). As in the case of the shallow wells, groundwater arsenic concentration in the deep wells exhibited no significant differences when compared across golf courses. In addition, arsenic concentrations in deep wells were not significantly different from background arsenic concentrations from wells of similar depth in the AWQM network. Data from the March 1999 sampling event indicated no significant change in arsenic concentration in groundwater.

Table 5: Summary Statistics for Arsenic in Deep (21-28 ft) Groundwater

Type of Site	(n)	Arsenic Concentration (ug/L)				% exceeding 2006 MCL
		Median	Mean	95%UCL	Range	
Briar Bay	12	1.00	9.9	18.6	1.0-44.0	33.3%
Palmetto	12	1.00	2.3	3.4	1.0-6.0	0%
Key Biscayne	12	1.00	3.6	6.2	1.0-11.3	16.7%
Golf Club	12	1.00	1.8	2.6	1.0-4.0	0%
Greynolds Park	12	3.00	5.0	8.3	1.0-19.0	25%
Total	60	1.00	4.5	9.1	1.0-44.0	18%
Background*	26	2.1	2.5	3.6	1.0-7.0	0%

Values reported as BDL are assigned the value of 1 ug/L (½ the method detection limit)

* Historical data from wells of similar depth (21-27 ft) in the AWQM network

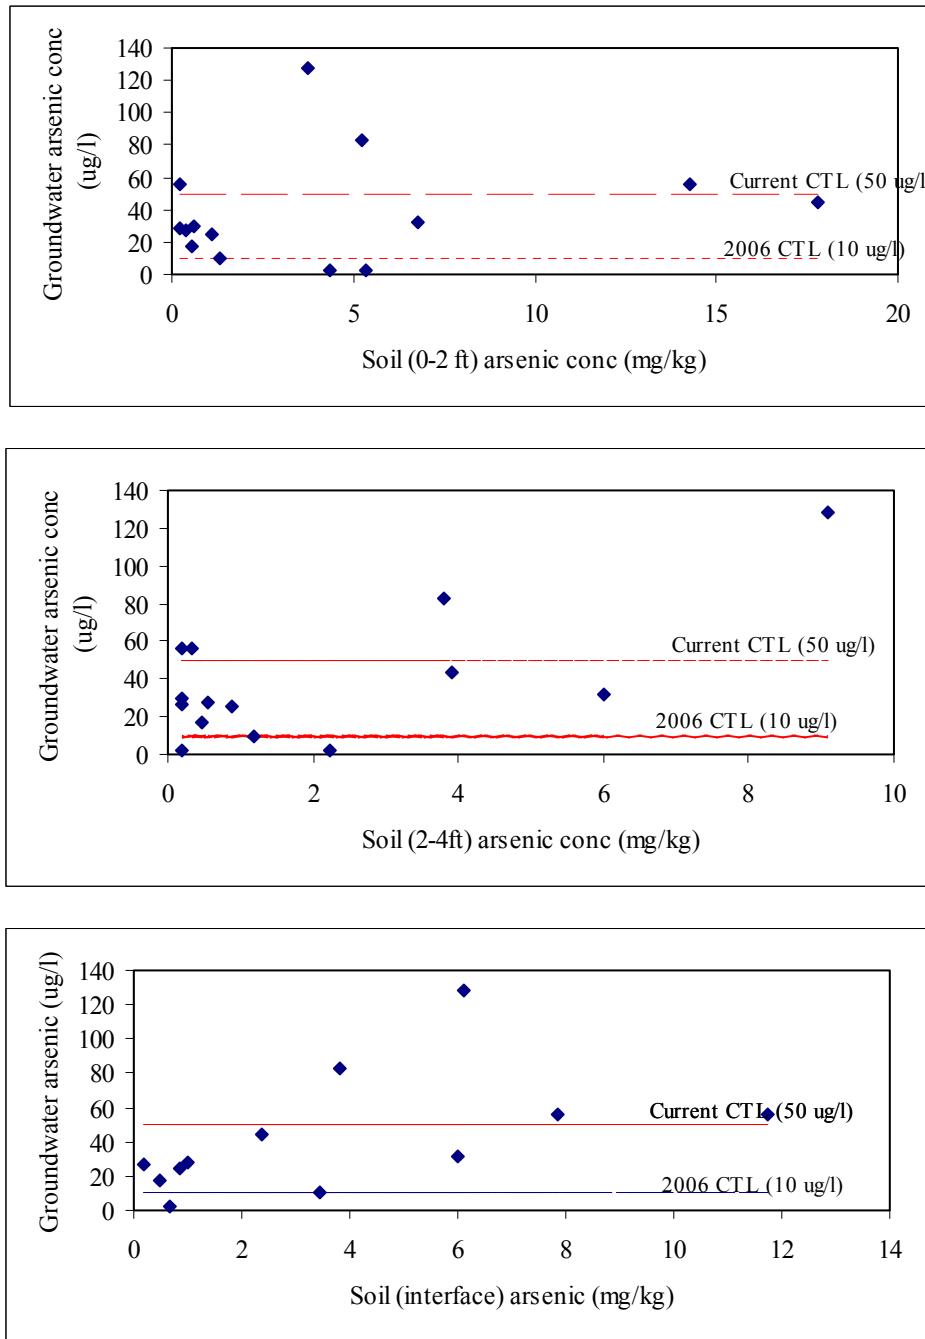

Soil versus Groundwater Arsenic Concentrations

Analysis of the arsenic data from shallow subsurface soil samples (0-2 ft) obtained during monitoring well installation versus groundwater data obtained from the shallow wells during the first quarter sampling event indicates no significant correlation ($\rho = 0.143$, $P > 0.05$). However, shallow groundwater arsenic concentration is positively correlated with arsenic concentration in soils at the soil/water interface ($\rho = 0.732$, $P < 0.05$).

The data were analyzed for linearity between soil arsenic concentrations from two feet intervals in the soil column and arsenic concentration in shallow wells; as shown in Figure 6, the data sets are not linearly related at any interval.

The soil core and groundwater arsenic data obtained during the first sampling event (Feb 1997), were analyzed to determine if the soil leachability CTL (29 mg/kg) for arsenic accurately estimates the potential for groundwater impact from overlying arsenic impacted soils. The February soil and groundwater data set were used since they represented spatially and temporally related data. Arsenic exceeded the groundwater CTL in twenty nine percent (29%) of the samples; but, none of soil samples exceeded the groundwater leachability CTL. Likewise, the data was examined based on the 2006 groundwater CTL and the corresponding soil leachability CLT of 5.8 mg/kg; eighty percent (80%) of the groundwater samples exceed the 2006 CTL; however, only twenty-three percent (23%) of the soil samples were above 5.8 mg/kg.

Figure 6: Soil arsenic concentration at different intervals in the soil profile versus February 1997 groundwater arsenic concentration from shallow wells

As indicated in Figure 6, groundwater impact above the CTL occurs at soil arsenic concentrations well below the leachability CTL. It is important to note that an examination of arsenic concentrations in groundwater underlying soils with arsenic concentration <5 mg/kg reveals that, for the soil intervals presented in Figure 6 (0-2, 2-4 and groundwater/soil interface) sixty seven percent, seventy seven percent and seventy five percent respectively, of the groundwater samples exceeds the 2006 CTL. At soil concentrations <2 mg/kg the percentages of

groundwater samples exceeding the 2006 CTL are fifty seven (57%), seventy eight (78%) and eighty (80%) for the respective soil intervals.

The conclusion is that the soil leachability CTL fails to predict the potential for arsenic to leach from overlying soils. It does not appear that there is a trigger soil arsenic concentration that can reliably predict the potential for groundwater impact. This conclusion is consistent with data from golf courses elsewhere in south Florida where groundwater impact was also observed when soil concentrations were below the leachability CTL (FDEP, personal communication).

Arsenic Levels at Different Golf Course Areas

Mix/Load Sites

Monitoring sites were located at or in the vicinity of the agrichemical mixing and loading areas of all the participating golf courses. Utility obstacles at Golf Club of Miami and Key Biscayne Golf Course resulted in the wells being sited at less than optimal distances (200 ft and eighty-two feet respectively) from the mix/load sites. At Palmetto Golf Course, wells were placed adjacent to a new mix/load center. Based on the foregoing, the data from the mix/load sites at Briar Bay and Greynolds Park Golf Course are considered to be representative of historical impact and traditional mix/load sites and as such only these data sets are discussed. Data from all mix/load sites are presented in Table 6a.

All soil sample results from mix/load sites at Briar Bay and Greynolds Park golf courses exceeded the residential CTL. The soil sample collected from the 0-2 ft interval of the mix/load site at the Briar Bay Golf Course, had an arsenic concentration of 120.65 mg/kg which is over nine times the inter-quartile range for soil samples obtained during the study. While this data point was considered an outlier for the purposes of data analysis, it is considered valid and retained for discussion purposes since it is consistent with arsenic concentrations found in soils at mix/load sites at golf courses outside of the study (DERM files). There were not enough data points to perform a comparative statistical analysis of arsenic concentration in soils at mix/load sites. Shallow well samples from the mix/load sites consistently exceeded the arsenic MCL with the median concentrations at 519 ug/L and 181 ug/L, respectively (Table 6b, Figure 7a,b,c,d). Arsenic was elevated and significantly different from background in the samples from the deep wells at, but the current MCL was not exceeded. Twenty-one percent of these samples exceeded the 2006 MCL. Arsenic concentrations in shallow well samples, collected during March of 1999 from the mix/load sites were within the range of concentrations experienced during 1997.

Table 6a: Summary Statistics Arsenic at Mix Load Site

Sample Type	Depth	N	Arsenic Concentration			25 th Percentile	75 th Percentile
			Min	Max	Median		
Soil (mg/kg)	Surficial	6	5.60	33.50	11.70	7.62	19.25
	Column	12	0.20	9.10	4.43	1.84	6.27
Water (ug/L)	Shallow	20	1.00	815.0	31.8	20.65	354.75
	Deep	20	1.00	44.00	1.00	1.00	13.75

Table 6b: Summary Statistics for Arsenic at Mix Load Site (Briar Bay and Greynolds Park)

Site	Sample type	Depth	N	Arsenic Concentration			25 th Percentile	75 th Percentile
				Min	Max	Median		
Briar Bay	Soil	Surficial	2	8.3	9.6	8.95	8.63	9.28
		Column	1	4.52			na	
	Ground water	Shallow	4	455.00	815.00	519.00	470.75	741.25
		Deep	4	15.00	44.00	24.85	17.18	39.50

		Core	4	3.72	9.10	7.26	5.50	8.58
	Ground water	Shallow	4	128.00	243.00	181.00	129.75	239.00
		Deep	4	3.00	19.00	9.80	4.65	16.75

Figure 7a and 7b: Arsenic concentration in soil samples from mix/load sites

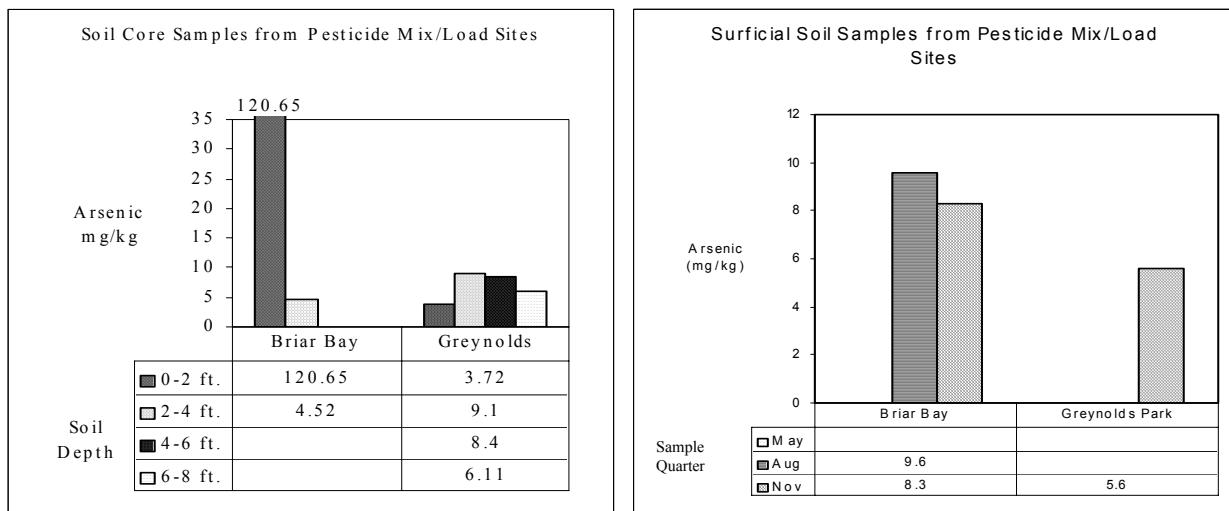

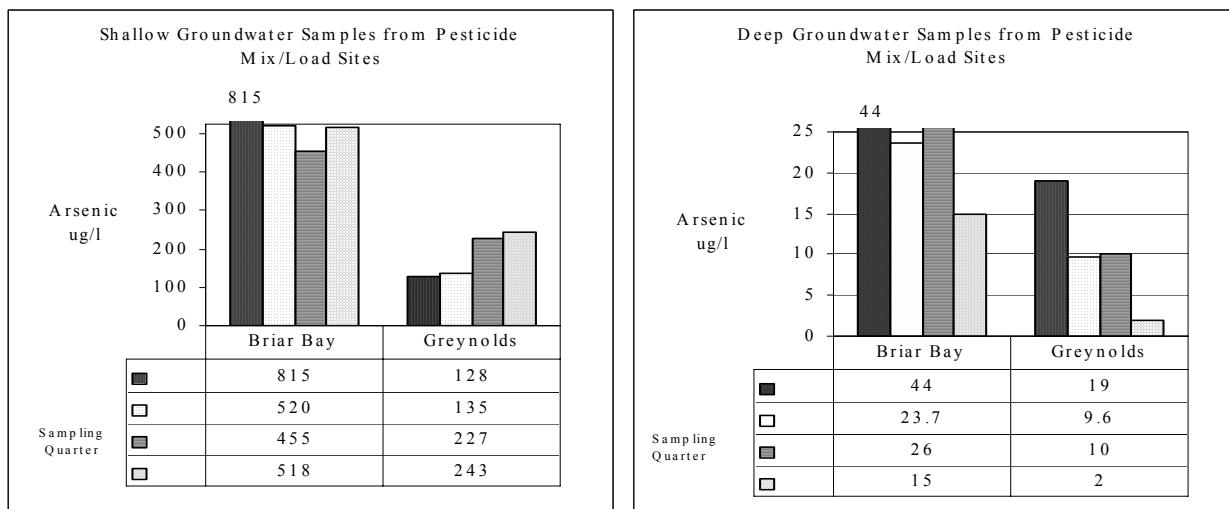

Figure 7c and 7d: Arsenic concentration in groundwater at mix/load sites

Arsenic at Fairway Sites

Summary statistics for arsenic concentrations at four monitored fairway sites are provided in Table 7. Arsenic was detected at levels exceeding both the residential CTL in forty five percent (45 %) and industrial CTL in thirty-six (36%) of the soil core samples from fairway sites. Arsenic levels in surficial soils exceeded both the residential and industrial CTL in all samples (Figure 8a and b).

Table 7: Summary Statistics for Arsenic at Fairway Sites

Sample Type	Depth	N	Arsenic Concentration				
			Minimum	Maximum	Median	25 th percentile	75 th percentile
Soil (mg/kg)	Surficial	9	13.10	34.6	27.5	14.4	29.1
	Core	11	0.1	14.28	0.34	0.1	7.85
Water (ug/L)	Shallow	16	1.00	56.00	17.75	1.00	29.85
	Deep	16	1.00	6.00	1.00	1.00	3.00
Background	Shallow	22	1.00	13.9	2.00		
	Deep	26	1.00	7.00	2.10		

Arsenic was elevated over background in the shallow groundwater at several fairway sites; however, the current MCL was exceeded only twice, once at Palmetto and once at Briar Bay Golf Course. The exceedence of the current MCL at Briar Bay Golf Course fairway #4 during the first sampling event was inconsistent with the trace levels detected in subsequent samples (Figure 8c). Shallow fairways wells at Key Biscayne and Palmetto consistently exceeded the 2006 MCL for arsenic.

Figure 8a and 8b: Arsenic concentration in core soil and surficial soil samples at fairway sites

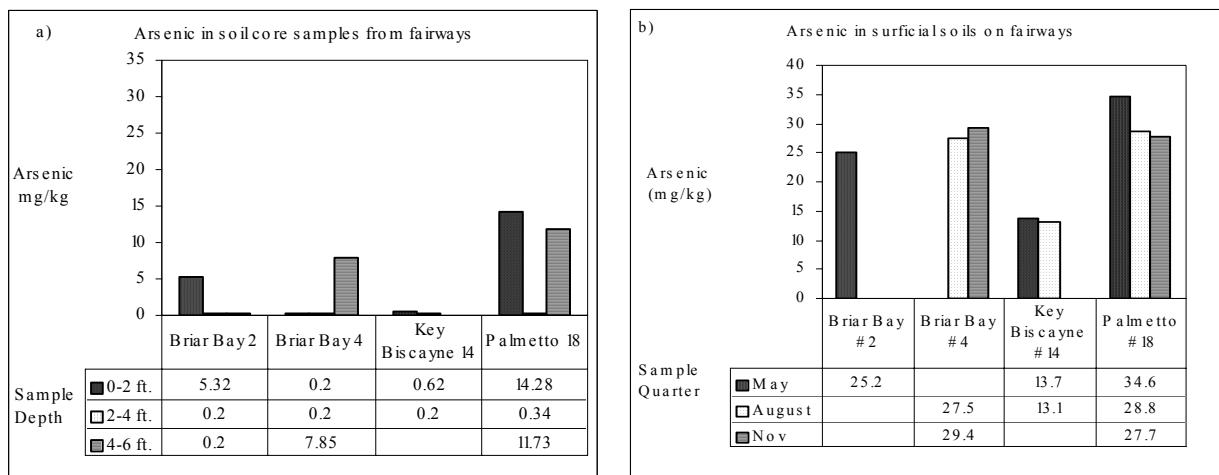

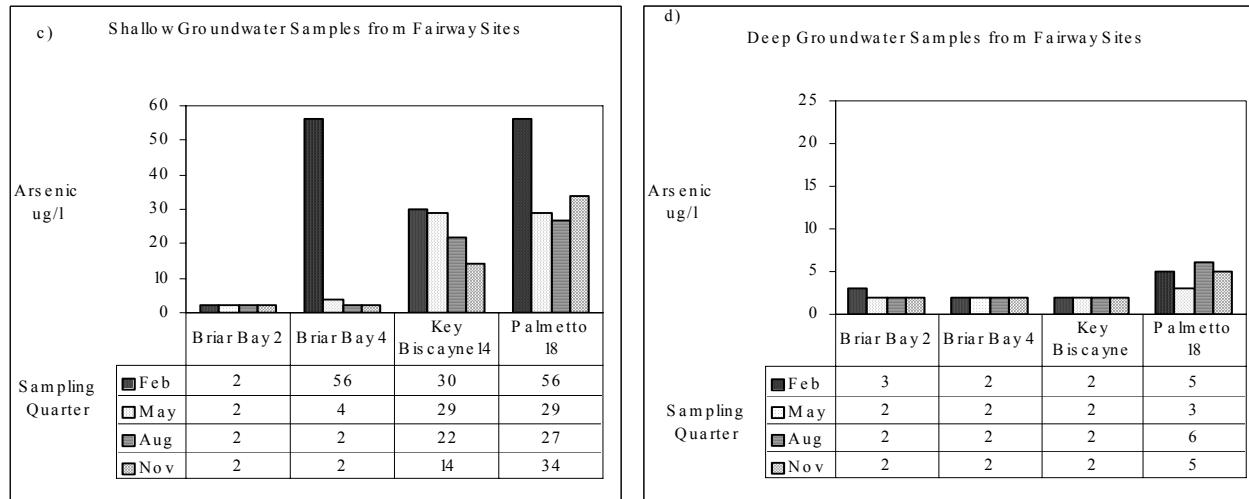

Figure 8c and 8d: Arsenic in groundwater (shallow and deep) at fairway sites

Arsenic was detected in trace amounts in thirty-one percent (31%) of the samples from deep wells (Figure 8d); however, neither the current nor the 2006 MCL was exceeded. Groundwater arsenic concentration obtained at fairways in 1999 were generally within the range of concentrations reported in 1997; however, the shallow well sample from the fairway at Key Biscayne (4.85 ug/L) indicated a significant decline from the 1997 concentrations.

Arsenic Levels at Green Sites

The residential soil CTL was exceeded in sixty-six (66%) of the soil column samples from green sites. Only one such sample exceeded the industrial CTL (Figure 9a.). In contrast, all but one surficial soil sample from greens exceeded the residential criteria and fifty (50%) exceeded the industrial criteria (Figure 9b.). The green at Greynolds Park had the highest surficial soil arsenic concentrations. Summary statistics for arsenic concentrations in soil and groundwater at green sites are provided in Table 8.

Table 8: Summary Statistics for Arsenic at Green Sites

Sample Type	Depth	N	Arsenic Concentration			25 th percentile	75 th percentile
			Minimum	Maximum	Median		
Soil (mg/kg)	Surficial	7	0.8	40.4	4.30	1.80	32.8
	Core	9	0.1	6.0	1.11	0.49	2.38
Water (ug/L)	Shallow	12	6.5	55.0	13.55	10.5	23.97
	Deep	12	1.00	4.0	1.00	1.00	3.75

Arsenic levels in shallow wells on greens ranged from 7–55 ug/L, with only a single exceedence of the current MCL; however, seventy-five (75%) of these samples exceeded the 2006 MCL. Arsenic was detected in trace amounts at some of the deep wells (Figures 9c, d), but none of the samples exceeded either MCL. Data obtained from green sites during the 1999 sampling event

were consistent with the 1997 data except at Greynolds Park Golf Course where arsenic concentration in shallow groundwater declined to BDL.

Figure 9a and 9b: Arsenic in soil core and surficial soil samples at green sites

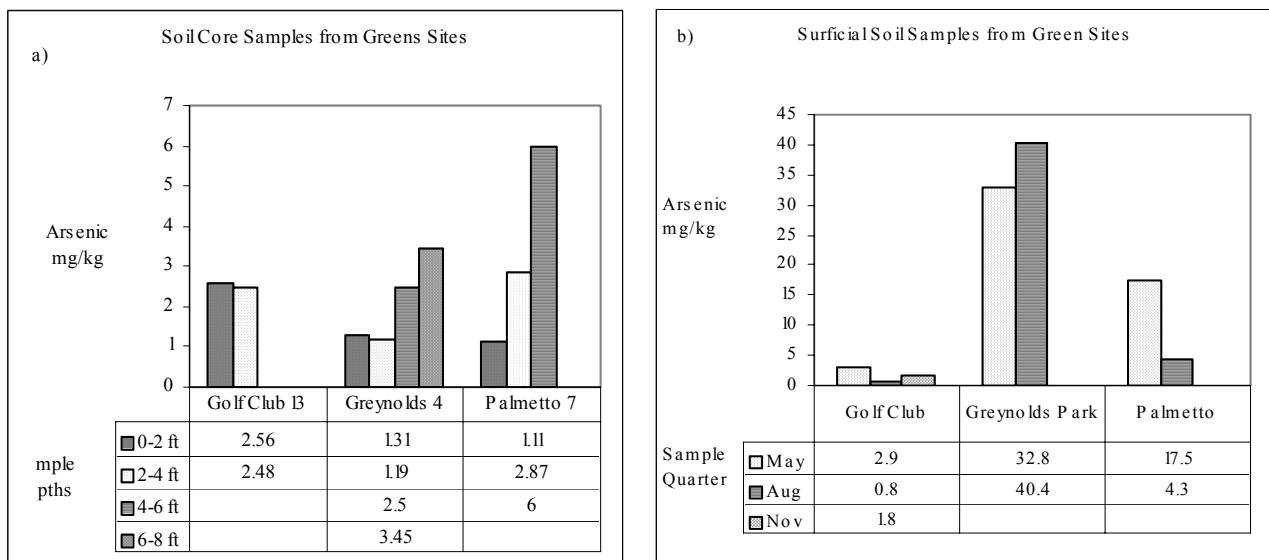

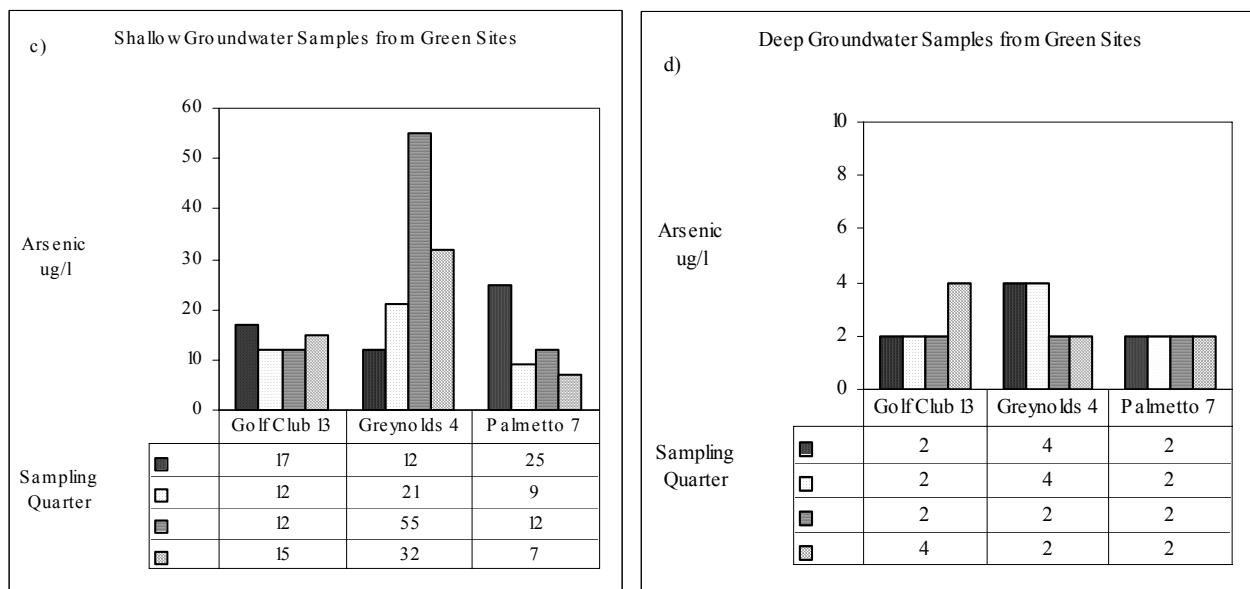

Figure 9c and 9d: Arsenic in groundwater (shallow and deep) at green sites

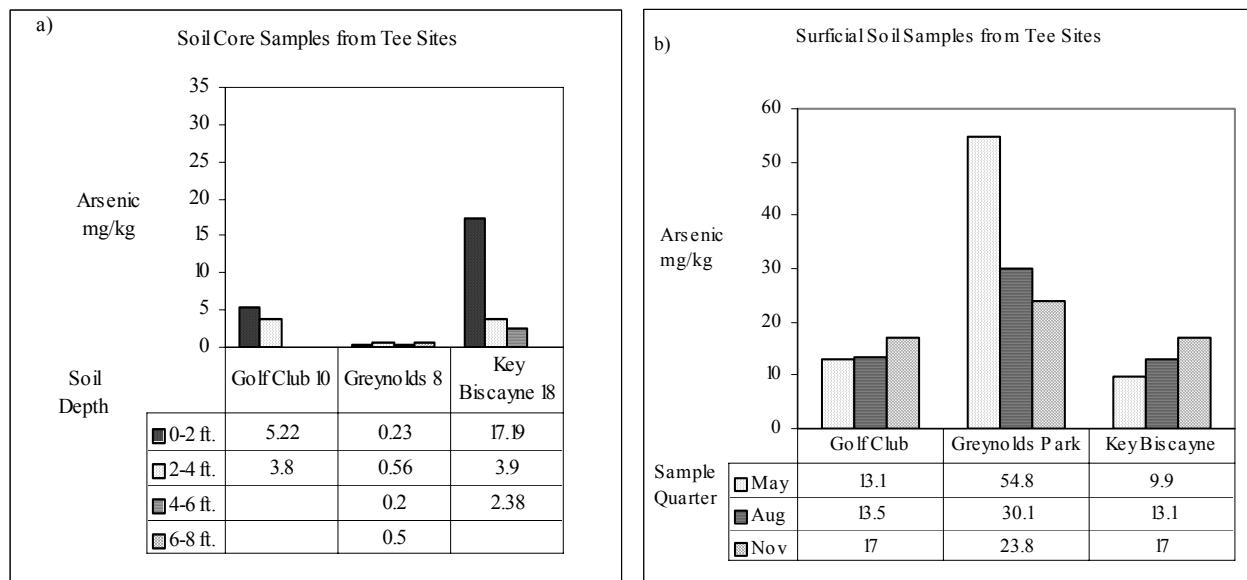

Arsenic Levels at Tee Sites

Three tee sites were monitored during the study; summary statistics for arsenic concentrations in soil and groundwater at tee sites are provided in Table 9. Soil arsenic levels from soil column samples ranged from BDL to 17.19 mg/Kg with thirty eight (38%) and thirty (30%) of the samples exceeding the residential and industrial soil CTLS, respectively (Figure 10a). Arsenic levels in all the surficial soil samples exceeded both the residential and industrial soil CTLS (Figure 10b). Values ranged from 9.9 to 54.8 mg/Kg.

Table 9: Summary Statistics for Arsenic at Tee Sites

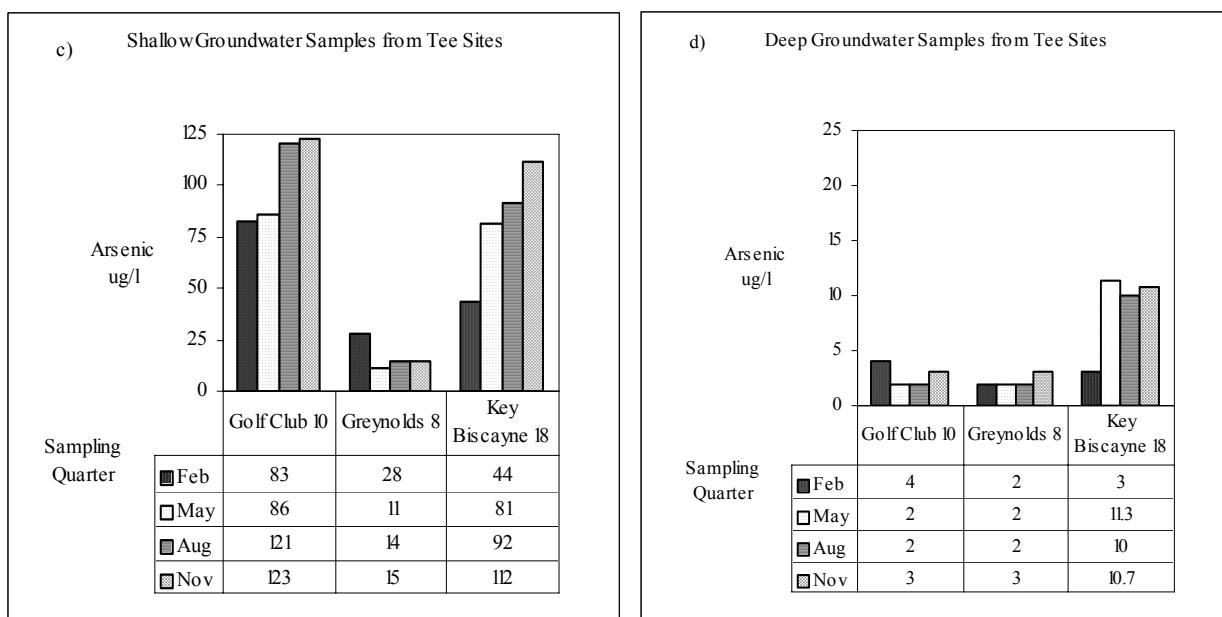

Sample Type	Depth	N	Arsenic Concentration			25 th percentile	75 th percentile
			Minimum	Maximum	Median		
Soil (mg/kg)	Surficial	9	9.9	54.8	17.00	13.1	26.95
	Core	10	0.1	17.19	1.69	0.36	4.32
Water (ug/L)	Shallow	12	10.5	123.0	81.75	18.25	23.97
	Deep	12	1.00	11.3	3.00	1.00	8.50

Figure 10a and 10b: Arsenic concentration in soil core and surficial soil samples at tee sites

Fifty-eight percent (58%) of shallow well samples at tee sites exceeded the current MCL and all samples exceeded the 2006 MCL. Except for Key Biscayne Golf Course where three of four samples from deeper wells exceeded the 2006 MCL, only trace concentrations of arsenic were detected at the other tee sites (Figure 10c and d). Arsenic concentration was elevated above the 1997 levels in the shallow well sample obtained from the tee at Golf Club of Miami during the 1999 sampling event.

Figure 10c and 10d: Arsenic in groundwater (shallow and deep) at tee sites

Comparison of Arsenic Concentration at Mix/Load sites and Play Areas

The occurrence of agrichemicals in soils and groundwater at mix/load sites is likely to reflect inputs from spills and discharges, whereas occurrence in the play areas is assumed to result in large part from applications of agrichemicals in accordance with label instructions. Based on the above, the loading rates of agrichemical to the environment in these two areas are expected to differ and this is expected to produce differences in contaminant levels in these two areas. The data were analyzed to determine if arsenic concentrations in soil and groundwater at mix/load areas was significantly different from concentrations encountered at the play areas.

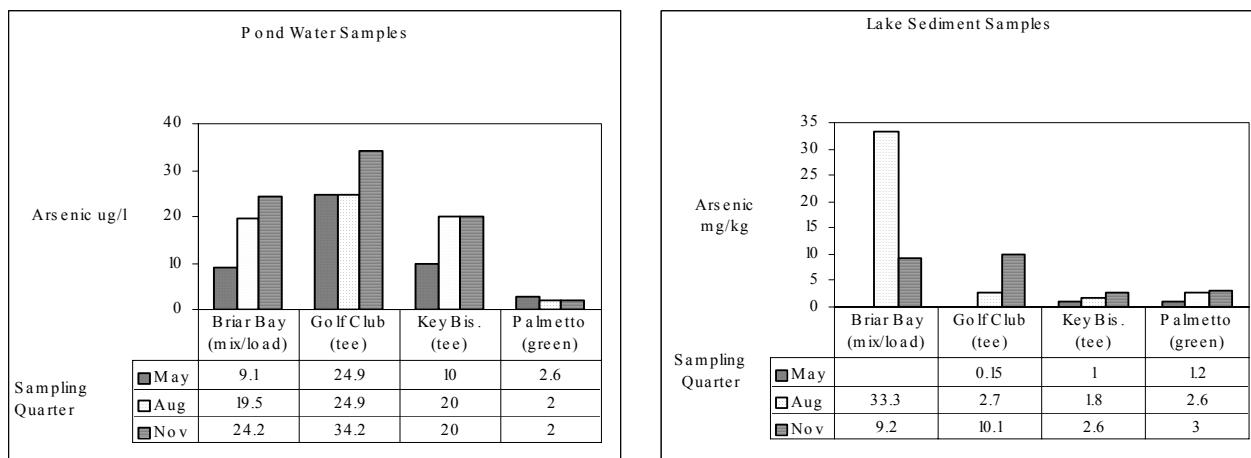

Kruskal-Wallis analyses of soil arsenic concentrations in the soil column indicated no statistically significant differences between the mix/load sites and the play areas. There were only three data points for surficial samples from mix/load sites and therefore no statistical comparison was made for surficial soils.

With respect to shallow groundwater, the Mann-Whitney test indicated that the population from mix/load sites was different from tees, green, and fairways. When the data from the three play areas were compared, using the Dunn test, tee sites were found to be significantly different from greens and fairways however, greens and fairways were not statically different populations. The statistical implication is that there are three separate populations with respect to groundwater arsenic concentration, mix/load sites, tees, and greens and fairways combined. The difference in arsenic concentration in the environment at tees and greens can be partially explained base on application patterns: since arsenical herbicides are typically not applied extensively to greens (personal communication) because the high turfgrass density on greens acts as a barrier to invading undesirable grass species. Tees and fairways are reported to have similar application patterns and so are expected to have similar levels of impact.

Arsenic in Surface Water and Sediments

During the last three sampling quarters in 1997, surface water and sediment samples were collected from ponds at four of the five golf courses and tested for total arsenic. Figure 11 presents the arsenic data for surface water and sediments. Concentrations of arsenic in surface water samples ranged from BDL (2 ug/L) to 34.2 ug/L, with a median concentration of 19.75 ug/L. There was no exceedence of the freshwater surface water CTL of 50 ug/L.

Figure 11: Arsenic Concentration in Surface Water and Sediment

The range of arsenic concentration in sediment samples was 0.15 mg/kg to 33.3 mg/kg; median concentration was 2.6 mg/kg. Surface water and sediment arsenic concentrations were not correlated at the P = 0.05 level.

Private Home Well Sampling

In January 1998, based on the detection of arsenic in the groundwater at the golf courses in the study, the Florida Department of Health (FDOH), at the request of the FDEP, sampled nine private home wells within a 0.25-mile radius of the Palmetto and Briar Bay Golf Courses for arsenic. Palmetto Golf Course and Briar Bay Golf Course were the only golf courses in the study with documented private home wells located in adjacent neighborhoods. Well depths were assumed to be within the range that is typical for private home wells (20-50 ft). Arsenic was detected in 8 samples at concentrations (0.14 – 0.59 ug/L) well below that detected in groundwater at golf courses and consistent with observed background groundwater arsenic concentrations.

In addition, DERM staff conducted a search for private home wells adjacent to all other golf course (i.e. golf courses not participating in the study). Only one golf course, located in the South Dade agricultural area, had adjacent residences served by private potable wells. Five private home wells from residences adjacent to this course were sampled. All samples were below detection level for arsenic.

Arsenic in Fertilizers

Fourteen fertilizer samples were collected from the five participating golf courses and analyzed for arsenic as another potential source to the golf course environment. The levels of arsenic in the fertilizer formulations tested ranged from BDL to 15 mg/kg (Table 10) with a mean concentration of 3.27 mg/kg.

Table 10: Arsenic Concentration in Fertilizer Formulations Used at Five Golf Courses

Sampling Location	Nitrogen Source	Proportions N P K	Arsenic (mg/Kg)
Golf Club of Miami	Ammoniated phosphate, polymer coated urea, sulfate of ammonia, muriate of potash, potassium nitrate, sulfate of potash	18-6-18	2
	Activated sludge, polymer coated urea, ammoniated phosphate, sulfate of potash, sulfate of potash-magnesia, sulfur coated urea	14-2-14	1
	Sulfate of potash, copper oxide, iron oxide, manganese sulfate, manganese oxide, zinc oxide, sodium borate, iron sulfate	8-10-10	4.3
	Ammoniated phosphate, polymer coated urea, potassium nitrate, sulfate of ammonia, sulfate of potash, muriate of potash	18-6-18	2
Greynolds Park Golf Course	Sulfate of ammonia, di-ammonium phosphate, sulfate of potash, sulfate of potash-magnesia, sulfur coated urea, manganese oxide, iron oxide	16-04-08	6.9
	Sewage sludge, packaged for retail use as a soil amendment		6.8
	Sulfate of ammonia, activated sludge, sulfate of potash, magnesium sulfate	10-00-10	2.7
Palmetto & Briar Bay Golf Courses	Sewage sludge, sulfur coated urea, triple super phosphate, sulfate of potash, sulfate of potash-magnesia	12-3-12	2
	Sulfate of ammonia		0.8
	Poly coated urea, coated urea, monoammonium phosphate, sulfate of potash, iron oxide, iron sulfate, manganese oxide	21-4-11	2
	Sulfur coated urea		BDL
Key Biscayne Golf Club	Poly coated sulfur coated urea, monoammonium phosphate, sulfate of potash, iron oxide, iron sulfate oxide, manganese sulfate	13-2-13	15
	Sulfur coated urea		BDL
	Sulfate of ammonia		BDL

The range of arsenic concentration in the golf course fertilizers is within the range of concentrations found in agricultural fertilizers based on a 1999 study conducted by the EPA (EPA 1999). In addition to the potential for directly contributing arsenic to the environment at golf courses, the use of phosphate fertilizers can also affect arsenic mobility in soil. Phosphate competes with and displaces arsenic for soil sorption sites resulting in increased arsenic mobility (Smith, et al 2002)

Pesticides

Pesticides in Groundwater

There were a total of twenty pesticide detections involving nine different pesticide residues. Nine of the detected concentrations were between the MDL and the PQL for the relevant analytical methodology. There were ten detections above the relevant PQL (Table 11) involving six pesticide residues (chlorothalonil, metribuzin, chlorpyrifos methyl, oxadiazon, atrazine, and dieldrin); only these are discussed further. The only pesticide detected at concentrations above the relevant groundwater guidance criteria was dieldrin.

Chlorothalonil was detected once at the mix/load site at Briar Bay Golf Course. Chlorothalonil is the active ingredient in various brands of board spectrum fungicide. Annual usage of chlorothalonil at golf courses in Miami-Dade County is reported as up to thirty gallons (personal communication, DERM files). There were three detections of metribuzin at Golf Club of Miami. Metribuzin is the active ingredient in Sencor, one of the preferred herbicides used at golf courses in Miami-Dade County.

Three compounds (oxadiazon, chlorpyrifos-methyl, and dieldrin) not originally targeted for study were found at concentrations above PQL in shallow groundwater at Golf Club of Miami. Oxadiazon detected at the Golf Club of Miami is a pre-emergent herbicide used in crabgrass and goosegrass control. This product is applied twice per year at the Golf Club of Miami.

Table 11: Pesticides Detected above PQL in Groundwater Samples					
Station ID	Well	Sampling Quarter	Concentration (ug/L)	Pesticide Residue	CTL (ug/L)
BBML	Shallow	4th	0.25	Chlorothalonil	3.18
GCML	Shallow	2nd	1.6	Metribuzin	175

GCT10	Shallow	4th	1.3	Metribuzin	175
GW 50	Back ground		0.48	Atrazine	3

Neither chlorpyrifos-methyl nor dieldrin are registered for use in turf management. Chlorpyrifos-methyl is an insecticide labeled for use on stored grain. Dieldrin is no longer registered for use in the United States; all uses were cancelled in 1987. However, dieldrin is very persistent in the environment, and as such, its presence at the Golf Club of Miami may be a remnant of historical usage unrelated to turf maintenance.

Atrazine was detected in one of the ambient background well, GW50, located in a residential area approximately one mile to the southeast of Golf Club of Miami. Atrazine is one of the most commonly used pesticides by volume in the United States and is one of the most frequently detected in groundwater nationally (EPA, 1997). It is widely used as a corn herbicide and as “weed and feed” products for use on lawns.

Seventy-five percent of the pesticides detected in groundwater during the study were detected at the Golf Club of Miami. This can be partially explained by the fact that this was the only golf course sampled for chlorinated pesticides during all four sampling events. Six of the nine pesticide residues detected were chlorinated pesticides.

Pesticides in Surface Water

Trace amounts of four pesticides; fonofos, atrazine, oxadiazon, and ethoprop were detected in surface water from golf course ponds (Table 12). Four of six pesticide detections in surface water occurred at the Golf Club of Miami with atrazine and oxadiazon detected twice. Fonofos (1.2 ug/L) and ethoprop (0.66 ug/L) detected at the Briar Bay and Palmetto Golf Courses, respectively, exceeded the freshwater surface water CTL. Pesticide inventory records from these golf courses indicates that fonofos was last used at the Briar Bay Golf Course in 1996 and there was no record of ethoprop use at the Palmetto Golf Course in the two years prior to the study. Oxadiazon is the only pesticide that was detected in both ground and surface water. Both detections occurred at the Golf Club of Miami.

Table 12: Pesticides Detected in Pond Samples

Near GW site	Station ID	Sampling Quarter	Concentration ug/L	Pesticide Residue	Surface water cleanup target level (ug/L)

Tee 10	GCL	Fourth	2.3	Oxadiazon	44
Tee 10	GCL	Fourth	0.47	Atrazine	1.8
Green 7	PML	Third	0.66	Ethoprop	0.315

Nutrient Components

Phosphate in Groundwater

Concentrations of total phosphate (TPO_4) in groundwater ranged from BDL (0.02 mg/l) to 1.07 mg/l. In general, the shallow wells had higher phosphate levels than deeper wells. The median phosphate concentration for shallow wells was 0.16 mg/l compared to 0.06 mg/l in the deeper wells. Phosphate levels in groundwater were elevated over median background concentrations.

Historical data from the AWQMN (n=458) indicate background concentrations of phosphate in groundwater at 0.029mg/l.

Nitrates in groundwater

Eleven of fifty-two shallow groundwater samples exceeded the MCL of 10 mg/l for nitrates. The highest nitrate concentration was encountered at the mix/load site at Greynolds Park Golf Course (Figure 12). Median nitrate concentration in shallow wells (1.15 mg/l) was elevated above the median ambient background of 0.02 mg/l (n = 235). None of the deep well samples exceeded the MCL. Summary statistics for nitrates in groundwater are presented in Table 13.

Multiple comparison analysis (Dunn test) of nitrates in shallow groundwater from the different golf course areas indicated that mix/load sites and tees represent one statistical population while greens and fairways represent another. Mix/load sites typically double as areas used for washing equipment including fertilizer spreaders, which might contribute to the nitrate loading to the environment in these areas. Based on personal communication with golf course superintendents, fertilization rates for greens and tee are relatively similar and higher than for fairways. As such the statistical similarity between greens and fairways is unexpected.

Table 13: Summary Statistics for Nitrates in Groundwater

Type of Site	Well#	n	Min	Max	Median	25 th Percentile	75 th Percentile	# samples above MCL
Fairway	Shallow	15	0.01	8.28	0.26	0.02	0.49	None

	Deep	52	0.01	8.34	0.03	0.01	1.28	None

Nitrates and Phosphates in Ponds

Nutrients are a concern to the ecology of ponds since stormwater runoff from fertilized turf can cause eutrophication. There are no numerical surface water standards for nitrates or phosphates for non-potable surface waters (Class III). Nutrient concentrations encountered at golf course ponds were generally low. Nitrate concentrations ranged from below detection to 0.52 mg/l, while phosphates ranged from below detection to 0.23 mg/l (Table 14). None of the ponds showed visual evidence of excessive algal growth usually associated with eutrophic conditions.

Figure 12: Nitrate concentration in groundwater at golf courses in Miami-Dade County

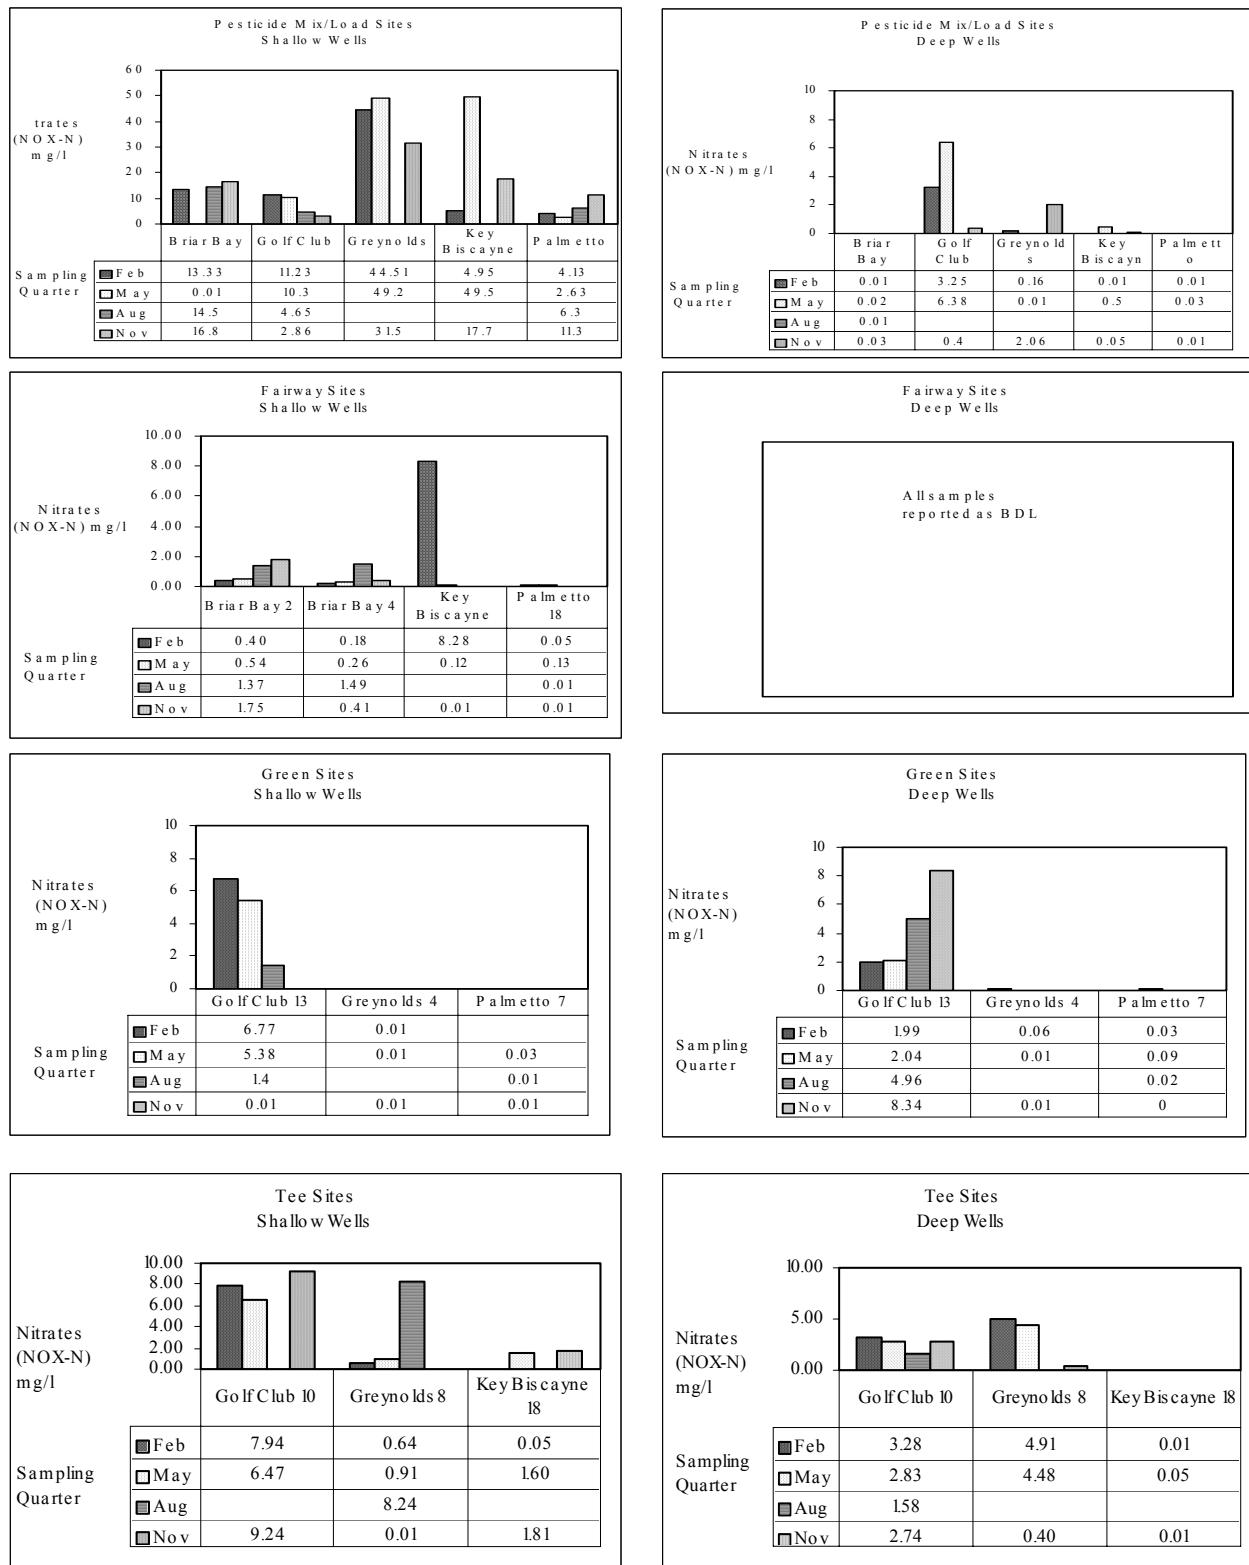

Table 14: Nutrient Concentration in Golf Course Ponds (data as mg/L)

	Sampling Quarter	Briar Bay	Golf Club	Key Biscayne	Palmetto
Nitrates	Second	0.07	0.17	0.07	0.06
	Third	<0.01	0.08	0.02	0.08

	Fourth	0.08	0.23	<0.02	<0.02

CONCLUSION

a. Arsenic

Soils from golf courses evaluated in this study generally contain concentrations of arsenic that are greater than those found in background areas. Ninety-four percent (94%) and eighty-seven percent (87%) of the surficial soil samples from golf courses exceeded the residential and industrial soil CTL. Soil boring samples contained elevated levels of arsenic from the surface down to the saturated zone.

Groundwater samples from the shallow monitoring wells at the study sites were also found to contain arsenic at levels greater than background. Thirty two percent of samples collected from wells near the water table (shallow wells) exceeded the current MCL and seventy seven percent exceed the 2006 MCL of 10 ug/L. On average, arsenic was undetected (MDL 2ug/L) in wells at depths of approximately twenty feet. Except for sites with heavier loading (mix/load areas and tees) arsenic concentrations in deeper wells were similar to background levels and did not exceed the MCL.

Few potable wells are located near golf courses and none of those sampled contained arsenic residues at concentrations different from background levels.

Arsenic levels in surface water samples did not exceed the freshwater surface water CTL; however, concentrations were often an order of magnitude greater than the levels typically encountered in other surface water bodies in Miami-Dade County.

Arsenic in the golf course environment may derive from agrichemical usage as well as other anthropogenic sources relating to current or previous land uses. In this study, the relative contributions from the various potential anthropogenic sources have not been ascertained; however, the patterns of arsenic occurrence suggests that current or past agronomic practices have played a significant role in elevated arsenic concentrations. It is known that arsenical herbicides have been used for an extended period at the golf courses, and fertilizers containing some arsenic residues have also been applied. Based on arsenic concentrations in shallow wells; golf courses include three statistically different populations: mix/load sites, tees, and greens and

fairways. Elevated levels of arsenic in play areas are assumed to result in large part from routine agrichemical application, whereas contamination at the mix/load sites is likely attributable to the incremental effect of deposition from past spills and/or equipment cleaning activities.

b. Pesticides

Generally, pesticides were detected in trace amounts in shallow wells and surface water. One pesticide residue, dieldrin, exceeded the groundwater CTL while fonofos and ethoprop exceeded the surface water CTL. In some cases the source of these pesticides cannot be linked to golf course turf management activities.

c. Nutrients

Groundwater at golf courses contains elevated concentration of nitrates with the highest concentrations associated with mix/loading areas. However, groundwater under the play areas on the courses also contains nitrates elevated above background. The distribution of nitrates in groundwater from the play areas appears to be consistent with routine turf management practices. Nitrate concentration in groundwater decreases from tees to greens to fairways. This coincides with relative fertilization rates.

RECOMMENDATIONS

1. The study documents the occurrence of arsenic in soils and groundwater at municipal golf courses. If resources allow, further assessment should determine the aerial extent of occurrence and evaluate the potential for offsite migration.
2. Arsenical agrichemicals used in routine turf management activities could be a source of arsenic in soil and groundwater. Further work is required to determine actual quantities used and to assess the environmental fate of these chemicals. The need for management practices to mitigate arsenic impact should be evaluated.
3. The data indicates that the current agrichemical mixing and handling practices significantly contribute to soil and groundwater contamination. Improved management practices should be explored to prevent contamination associated with agrichemical mix/loading and handling activities.
4. In order to fully characterize the sources of arsenic in the golf course environment, other potential sources such as fill material should be investigated.
5. A review of existing data should be conducted to assess arsenic levels in potable wells near golf courses. This review should determine whether additional sampling is needed to assess potential occurrence of arsenic in drinking water near golf courses.

6. Data from the study should be compared with available data from other parts of Florida to determine the actual magnitude of arsenic occurrence and to identify potentially vulnerable areas.

Study Site Descriptions

Key Biscayne Golf Course

The Key Biscayne Golf Course (recently renamed Crandon Golf Course) was established in 1972. This 18-hole PGA course occupies approximately 125 acres on the island of Key Biscayne located off the southeast coast of Miami-Dade County. It is bordered by Biscayne Bay on the west, Crandon Boulevard on the east, an area of undeveloped land to the north, and the Lipton Tennis Center to the south. (Figure 2)

Prior to the establishment of the golf course, the southern one-third of the property was used as a municipal dump for the island of Key Biscayne. The remainder of the property was undeveloped wetlands. The dump was closed during the 1970s (DERM files).

Soils in this area are of the St Augustine Series (NRCS Soil Survey). The St Augustine sands are somewhat poorly drained with less than two percent slope and a two to twenty percent (2-20%) permeability. Soils of this type typically contain of one to three percent organic matter.

Information obtained from lithology logs during well drilling for this project revealed a very distinct, fibrous, dusky brown, peat layer approximately 1 foot deep. This layer occurred at a depth of approximately 6 feet below land surface (bls). This layer had a very swampy odor and is probably derived from mangrove debris. A layer of limestone fragments and sand overlie the peat. This layer could be fill material. Subtending the peat to a depth of about twenty two feet is a layer of dark brown soupy sand. A limestone formation is beneath the sand layer.

The groundwater beneath the golf course is subject to tidal influences; especially to the west where the play areas are sometimes located within thirty feet of the Biscayne Bay. The chemistry of the groundwater reflects a tidal influence with specific conductivity readings as high as 15,900 uhs/cm along the western fringe. A conductivity gradient observed between shallow and deep wells, especially along the west side of the course, suggests that a lens of brackish to fresh water overlays more saline waters.

The land surface lies at approximately 5 feet above sea level with an average groundwater depth at approximately two feet above sea level. Localized groundwater flow appears to be northeasterly towards Biscayne Bay. The golf course uses utility water for irrigation since the salinity of the groundwater precludes its use. Utility water is piped into a retention lagoon from which it is distributed for irrigation. The golf course uses in excess of 130 million gallons of water per year. Although this figure includes total water usage for the golf course, it is reasonable to assume that most of that water is used for irrigation.

Golf Club of Miami

This golf course was established in 1962. It is 160 acres in size and is located in northwest Miami-Dade County. It is bordered on the south by Miami Gardens Drive and on all other sides by residential developments. The course actually meanders around several residential developments. The course is traversed by an FPL easement with high voltage power lines and an

underground jet fuel pipeline runs through the property. The course is located within 350 feet of the Peter Pike Canal on the north and west sides (Figure 2).

Soils in this area are broadly described as Udorthents and consist mainly of fill material over hard limestone substrata. These soils are moderate to well drained with a zero to five percent slope and are typically located in developed areas. The soils are considered well suited for golf courses (NRCS 1996).

Lithology information obtained during monitoring well installation indicates that the area consists of a soft, pale orange, sub rounded sand to approximately twenty two feet. The sand layer overlies a hard, fossilized limestone substratum thought to be the Fort Thompson Formation. Land surface elevation range from four to six feet above sea level (DERM topography data).

The golf course is irrigated using groundwater as well as water from the freshwater ponds on the golf course. There are four irrigation wells which extract water from the underlying Biscayne Aquifer. This water is supplemented for irrigation purposes with water from the ponds.

Briar Bay Golf Course

Briar Bay Golf Course, established in 1974, is a nine-hole facility that occupies approximately thirty acres. Established as a part of the Briar Bay subdivision it is located approximately one half mile west of US 1 (South Dixie Highway) in southwest Dade County. The C100C canal is located approximately 300 feet away and runs parallel to the golf course on the west and south sides (Figure 3)

Prior to 1971, the area supported very dense pineland vegetation. The pine forest was cleared between 1971 and 1972 to allow for the diversion of the C100C canal which had historically run parallel to SW 128 Street along what is currently the north side of the Briar Bay Golf Course. Between February and December of 1972, the C100C canal was diverted to its current location approximately 300 feet west of the golf course. Construction on the golf course began in 1973.

Soils in this area are Biscayne marl drained, and consist of five to twelve percent clay and one to two percent organic matter (NRCS 1996). These soils are shallow and poorly drained with moderate permeability. With regular applications of fertilizer, these soils are considered suitable for the growth of Bermuda grass (the preferred grass for golf course playing surfaces in the southeast United States).

Lithology information obtained during monitoring well installation for this study revealed that the upper four feet consisted of limestone fragments which appeared to be fill material overlying Miami Oolite, which occurs down to twenty-three feet. At twenty-three feet a harder formation of Key Largo limestone was encountered. Rock fragments from this layer consisted of conus and bryzoan fossils. There was indication of dolomite replacement with calcite crystals. Land surface elevation is between eight and ten feet above sea level (DERM topographic data) with average groundwater depth at approximately three feet above sea level.

The golf course is irrigated using groundwater supplied by a single irrigation well that produces from the Biscayne Aquifer. Groundwater measurements obtained during the study suggest that localized groundwater flow is in a northerly direction.

Palmetto Golf Course

Established in the early 1960s the golf course occupies approximately 120 acres in southwest Miami-Dade County. The golf course is surrounded on the west and south by residential development and on the east and north by South Dixie Highway and Coral Reef Drive, respectively (Figure 4).

Aerial photographs from the 1950s indicate that the area was farmed prior to being developed as a golf course. The C100 canal traverses the property in an approximate northwest to southeast direction. The Soil Survey of Dade County describes soils in this area as Udorthents consisting mainly of fill material over hard limestone substratum. These soils are usually associated with urban built up areas and are considered well suited for golf courses.

Lithology logs obtained during the study indicate that the area consists of a layer of silty to clayey sands down to approximately five feet. Miami oolite limestone subtends the sandy layer and extends to approximately twenty four feet. A layer of soft, pale yellow-orange lime mud occurs between twenty four and thirty, feet which was the maximum depth of drilling.

The golf course is located on the edge of the Atlantic Coastal Ridge and, as such, the land surface elevations here are the highest encountered during the study. This is especially true along the eastern perimeter of the course. Elevations ranged from twelve feet above sea level on the east side of the golf course to approximately eight feet on the north and southwest sides (DERM topography data).

Measurements obtained during the study indicate average groundwater depth at approximately four feet above sea level. Local groundwater flow appears to be northeasterly away from the canal. However, it seems logical to expect that on the west side of the course, especially adjacent to the canal of the course groundwater is influenced by the C100 canal.

The golf course is irrigated by groundwater extracted from the underlying Biscayne Aquifer. Two wells located within 500 feet of the canal on the northwest side of the golf course supply water for irrigation.

Greynolds Park Golf Course

This golf course was established in the 1950s as a part of the Greynolds Park recreation and preservation area in northeast Miami-Dade County. The nine-hole golf course occupies 50 acres on the southwest side of the park and is surrounded by residential development on the north, west, and south sides (Figure 5). The park itself lies just north of the Oleta River State Recreation area and consists of wetlands and oak mixed with slash pine vegetation. The Oleta River forms the eastern boundary of the park.

Soils in this area are Dade fine sand and are described as well drained with smooth slopes (less than two percent) with very high permeability, (< 20 inch/hr). These soils typically consist of zero to five percent clay and zero to five percent organic matter. They are considered well suited for the growth of Bermuda grass when properly managed.

Since the site sits on the Atlantic Coastal Ridge, it is one of the highest points in Miami-Dade County. Elevations on site range from 9 to 10 feet above sea level (DERM topography data).

Lithology information obtained from the site indicates two feet of organic material overlying pale orange limestone, down to at least thirty feet on the north side of the course. In the more southern areas of the course, four to six feet of light gray to orange sand overlies the limestone bedrock. The limestone formation is believed to be Miami Oolite.

The golf course is irrigated using water from the underlying Biscayne Aquifer which is accessed using three irrigation wells on site. Approximately seventy million gallons of water are used for irrigation each year. Water level measurements obtained during the study reveal average groundwater depth at approximately two feet above sea level, with an easterly flow towards the Oleta River.

DATA TABLES

APPENDIX C-E:

Laboratory Abbreviations and Field Codes

- A- Value reported is the mean of two or more determinations
- B- Results based on colony counts outside of the acceptable range
- I- Value reported is less than the minimum quantification limit, and greater than or equal to the minimum detection limit
- J- Estimated value
- K- Actual value is known to be less than value given
- L- Actual value is known to be greater than value given
- N- Presumptive evidence of presence of material
- O- Sampled but analysis lost or not performed
- T- Value reported is less than criterion of detection
- U- Material was analyzed for but not detected; the value reported is the minimum detection limit
- V- Analyte was detected in both sample and method blank
- Z- Colonies too numerous to count

- Ns- Not sampled
- Na- Not analyzed
- Ls- Sampled but samples lost or destroyed prior to analysis
